## 22 **NATIONAL CYBERSECURITY CENTER OF EXCELLENCE**

23 The National Cybersecurity Center of Excellence (NCCoE), a part of the National Institute of Standards  
24 and Technology (NIST), is a collaborative hub where industry organizations, government agencies, and  
25 academic institutions work together to address businesses' most pressing cybersecurity issues. This  
26 public-private partnership enables the creation of practical cybersecurity solutions for specific  
27 industries, as well as for broad, cross-sector technology challenges. Through consortia under  
28 Cooperative Research and Development Agreements (CRADAs), including technology partners—from  
29 Fortune 50 market leaders to smaller companies specializing in information and operational technology  
30 security—the NCCoE applies standards and best practices to develop modular, adaptable example  
31 cybersecurity solutions using commercially available technology. The NCCoE documents these example  
32 solutions in the NIST Special Publication 1800 series, which maps capabilities to the NIST Cybersecurity  
33 Framework and details the steps needed for another entity to re-create the example solution. The  
34 NCCoE was established in 2012 by NIST in partnership with the State of Maryland and Montgomery  
35 County, Maryland.

36 To learn more about the NCCoE, visit <https://www.nccoe.nist.gov/>. To learn more about NIST, visit  
37 <https://www.nist.gov/>.

## 38 **NIST CYBERSECURITY PRACTICE GUIDES**

39 NIST Cybersecurity Practice Guides (Special Publication 1800 series) target specific cybersecurity  
40 challenges in the public and private sectors. They are practical, user-friendly guides that facilitate the  
41 adoption of standards-based approaches to cybersecurity. They show members of the information  
42 security community how to implement example solutions that help them align with relevant standards  
43 and best practices, and provide users with the materials lists, configuration files, and other information  
44 they need to implement a similar approach.

45 The documents in this series describe example implementations of cybersecurity practices that  
46 businesses and other organizations may voluntarily adopt. These documents do not describe regulations  
47 or mandatory practices, nor do they carry statutory authority.

## 48 **ABSTRACT**

49 The Industrial Internet of Things, or IIoT, refers to the application of instrumentation and connected  
50 sensors and other devices to machinery and vehicles in the transport, energy, and other critical  
51 infrastructure sectors. In the energy sector, distributed energy resources (DERs) such as solar  
52 photovoltaics and wind turbines include sensors, data transfer and communications systems,  
53 instruments, and other commercially available devices that are networked together. DERs introduce  
54 information exchanges between a utility's distribution control system and the DERs to manage the flow  
55 of energy in the distribution grid.

56 This practice guide explores how information exchanges among commercial- and utility-scale DERs and  
 57 electric distribution grid operations can be monitored and protected from certain cybersecurity threats  
 58 and vulnerabilities.

59  
 60 The NCCoE built a reference architecture using commercially available products to show organizations  
 61 how several cybersecurity capabilities, including communications and data integrity, malware detection,  
 62 network monitoring, authentication and access control, and cloud-based analysis and visualization can  
 63 be applied to protect distributed end points and reduce the IIoT attack surface for DERs.

64 **KEYWORDS**

65 *data integrity; distributed energy resource; industrial internet of things; malware; microgrid; smart grid*

66 **ACKNOWLEDGMENTS**

67 We are grateful to the following individuals for their generous contributions of expertise and time.

## 132 1 Summary

133 An increasing number of distributed energy resources (DERs) are connecting to the distribution grid.  
134 These DERs introduce two-way information exchanges between a utility's distribution control system  
135 and the DERs, or an aggregator, to manage the flow of energy in the distribution grid. These information  
136 exchanges often employ Industrial Internet of Things (IIoT) technologies that lack the communications  
137 security present in conventional utility systems. Managing, trusting, and securing the information  
138 exchanges between and among DERs present significant challenges.

139 The National Institute of Standards and Technology's (NIST's) National Cybersecurity Center of  
140 Excellence (NCCoE) collaborated with stakeholders in the electricity sector, the University of Maryland  
141 (UMD), and cybersecurity technology vendors to build a laboratory environment that represents a  
142 distribution utility interconnected with a campus DER microgrid. Using this environment, we are  
143 exploring how information exchanges between commercial- and utility-scale DERs and the electric  
144 distribution grid can be monitored, trusted, and protected.

145 The goals of this NIST Cybersecurity Practice Guide are to help organizations:

- 146     ▪ remotely monitor and control utility-owned and customer-managed DER assets
- 147     ▪ protect and trust data and communications traffic of grid-edge devices and networks
- 148     ▪ capture an immutable record of control actions across DERs
- 149     ▪ support secure edge-to-cloud data flows, visualization, and continuous intelligence

150 For ease of use, the following provides a short description of each section in this volume.

151 Section 1, Summary, presents the challenge addressed by this NCCoE project, including our approach to  
152 addressing the challenge, the solution demonstrated, and the benefits of the solution.

153 [Section 2](#), How to Use This Guide, explains how business decision makers, program managers,  
154 information technology (IT) and operational technology (OT) professionals might use each volume of the  
155 guide.

156 [Section 3](#), Approach, offers a detailed treatment of the scope of the project, the risk assessment that  
157 informed the solution, and the technologies and components that industry collaborators supplied to  
158 build the example solution.

159 [Section 4](#), Architecture, specifies the components of the example solution and details how data and  
160 communications flow between and among DERs and the distribution grid.

161 [Section 5](#), Security Characteristic Analysis, provides details about the tools and techniques used to test  
162 and understand the extent to which the project example solution meets its objective of demonstrating

163 that information exchanges among DERs and electric distribution grid operations can be monitored and  
164 protected from certain cybersecurity compromises.

165 [Section 6](#), Future Project Considerations, is a brief treatment of other applications that NIST might  
166 explore in the future to further protect DER communications.

167 The appendixes provide acronyms, a glossary of terms, and a list of references cited in this volume.

## 168 **1.1 Challenge**

169 Small-scale DERs—such as wind and solar photovoltaics—are growing rapidly and transforming the  
170 power grid. The distribution grid is becoming a multisource grid of interconnected devices and systems  
171 driven by two-way data communication and power flows. These data and power flows often rely on IIoT  
172 technologies that are connected to both the DERs’ power production assets and various wireless  
173 networks. These edge devices have an embedded level of digital intelligence that allows DER assets to  
174 be monitored and tracked, and through the edge devices, share data on their status and communicate  
175 with other devices across DER networks and beyond.

176  
177 A distribution utility may need to remotely communicate with thousands of DERs—some of which may  
178 not even be owned or configured by the utility—to control the operating points and monitor the status  
179 of these devices. Many companies are not equipped to provide secure access to DERs and to  
180 monitor and trust the rapidly growing amount of data coming from them or flowing into them. The  
181 ability of utilities and DER operators to trust these information exchanges is essential to these  
182 companies’ business. Any disruption or manipulation of the data could have negative consequences on  
183 utility and DER operations, and on their customers. Securing DER communications will be critical  
184 to maintain the reliability of the distribution grid. Any attack that can deny, disrupt, or tamper with DER  
185 communications could prevent a utility from performing necessary control actions and could  
186 diminish grid resiliency.

## 187 **1.2 Solution**

188 The NCCoE collaborated with stakeholders in the electricity sector, UMD, and cybersecurity technology  
189 providers to build an environment that represents a distribution utility interconnected with a cam-  
190 pus DER microgrid. Within this ecosystem, we explore how information exchanges among DERs and  
191 electric distribution grid operations can be protected from certain cybersecurity compromises. The ex-  
192 ample solution demonstrates the following capabilities:

- 193     ▪ **communications and data integrity** to ensure that information is not modified in transit
- 194     ▪ **authentication and access control** to ensure that only known, authorized systems can exchange  
195       information
- 196     ▪ **command register** that maintains an independent, immutable record of information exchanges  
197       between distribution grid and DER operators

- 198       ▪ **malware detection** to monitor information exchanges and processing to identify potential  
199       malware infections
- 200       ▪ **behavioral monitoring** to detect deviations from operational norms
- 201       ▪ **analysis and visualization** processes to monitor data, identify anomalies, and alert operators

202       The example solution documented in the practice guide uses technologies and security capabilities from  
203       our project collaborators. The solution aligns with the security standards and guidelines of the NIST Cy-  
204       bersecurity Framework; NIST Interagency or Internal Report 7628 Revision 1: *Guidelines for Smart Grid*  
205       *Cybersecurity* [1]; and the Institute of Electrical and Electronics Engineers (IEEE) 1547-2018, *IEEE Stand-*  
206       *ard for Interconnection and Interoperability of Distributed Energy Resources with Associated Electric*  
207       *Power Systems Interfaces* [2].

### 208    **1.3 Benefits**

209    The NCCoE’s practice guide can help your organization:

- 210       ▪ develop a risk-based approach for connecting and managing DERs and other grid-edge devices  
211       that is built on NIST and industry standards
- 212       ▪ provide integrity of energy transactions by monitoring and protecting IIoT digital  
213       communications
- 214       ▪ enhance reliability and stability of the grid by better protecting DERs from a cyber attack
- 215       ▪ assure that distribution operators retain control of DERs independent of a cyber event
- 216       ▪ provide an immutable record of commanded actions and responses across all utility-owned and  
217       customer-managed DERs

## 218    **2 How to Use This Guide**

219    This is a preliminary draft of Volume B of a NIST Cybersecurity Practice Guide. Implementation of the  
220    example solution at the NCCoE is ongoing. The NCCoE is providing this preliminary draft to gather  
221    valuable feedback and inform stakeholders of the progress of the project. Organizations should not  
222    attempt to implement this preliminary draft.

223    When finalized, this NIST Cybersecurity Practice Guide will demonstrate a standards-based reference  
224    architecture and provide users with the information they need to replicate secure and trusted  
225    information exchanges in a DER environment. This reference architecture will be modular and can be  
226    deployed in whole or in part.

227    This guide will contain three volumes:

- 228       ▪ NIST Special Publication (SP) 1800-32A: *Executive Summary*

229       ▪ NIST SP 1800-32B: *Approach, Architecture, and Security Characteristics*—what we built and why  
230        **(you are here)**

231       ▪ NIST SP 1800-32C: *How-To Guides*—instructions for building the example solution **(planned for**  
232        **early summer 2021 release)**

233 Depending on your role in your organization, you might use this guide in different ways:

234 **Business decision makers, including chief security and technology officers,** will be interested in the  
235 *Executive Summary*, NIST SP 1800-32A, which describes the following topics:

236       ▪ challenges that enterprises face in monitoring, protecting, and trusting information exchanges  
237        among and between DERs

238       ▪ example solution built at the NCCoE and UMD

239       ▪ cybersecurity benefits of adopting the example solution

240 **Technology or security program managers** who are concerned with how to identify, understand, assess,  
241 and mitigate risk will be interested in this part of the guide, NIST SP 1800-32B, which describes what we  
242 did and why. The following sections will be of particular interest:

243       ▪ [Section 3.4.3, Risk](#), provides a description of the risk analysis we performed

244       ▪ [Section 3.4.4, Security Control Map and Technologies](#), maps the security characteristics of this  
245        reference architecture to cybersecurity standards and best practices and the technologies used  
246        in our example solution

247 You might share the *Executive Summary*, NIST SP 1800-32A, with your leadership team members to help  
248 them understand the importance of adopting standards-based cybersecurity for DERs.

249 **IT and OT professionals** who want to implement an approach such as this will find the entire practice  
250 guide useful. You can use the how-to portion of the guide, NIST SP 1800-32C, to replicate all or parts of  
251 the example solution created in our lab. The how-to portion of the guide will provide specific product  
252 installation, configuration, and integration instructions for implementing the example solution. We do  
253 not re-create the product manufacturers' documentation, which is generally widely available. Rather,  
254 we show how we incorporated the products together in our environment to create an example solution.

255 This guide assumes that IT and OT professionals have experience implementing security products within  
256 the enterprise. While we are using a suite of commercial products to address this challenge, this guide  
257 does not endorse these particular products. Your organization can adopt this solution or one that  
258 adheres to these guidelines in whole, or you can use this guide as a starting point for tailoring and  
259 implementing parts of the reference architecture to provide a high level of assurance in the integrity of  
260 the data for secure information exchanges between DERs and utilities. Your organization's security  
261 experts should identify the products that will best integrate with your existing tools and IT, OT, and  
262 related grid monitoring and control system infrastructure. [Section 3.4.4, Security Control Map and](#)

263 [Technologies](#), lists the products we used and maps them to the cybersecurity controls provided by this  
264 reference architecture.

265 A NIST Cybersecurity Practice Guide does not describe a "single" solution but rather a possible solution.  
266 This is a preliminary draft guide. We seek feedback on its contents and welcome your input. Comments  
267 and suggestions will improve subsequent versions of this guide. Please contribute your thoughts to  
268 [energy\\_nccoe@nist.gov](mailto:energy_nccoe@nist.gov).

## 269 2.1 Typographic Conventions

270 The following table presents typographic conventions used in this volume.

Typeface/Symbol	Meaning	Example
<i>Italics</i>	file names and path names; references to documents that are not hyperlinks; new terms; and placeholders	For language use and style guidance, see the <i>NCCoE Style Guide</i> .
<b>Bold</b>	names of menus, options, command buttons, and fields	Choose <b>File &gt; Edit</b> .
Monospace	command-line input, onscreen computer output, sample code examples, and status codes	<code>mkdir</code>
<b>Monospace Bold</b>	command-line user input contrasted with computer output	<code>service sshd start</code>
<a href="#">blue text</a>	link to other parts of the document, a web URL, or an email address	All publications from NIST's NCCoE are available at <a href="https://www.nccoe.nist.gov">https://www.nccoe.nist.gov</a> .

## 271 3 Approach

272 IIoT devices within DERs can communicate and exchange information across the open internet. Absent  
273 private communications networks, these information exchanges expand the attack surface of traditional  
274 energy generation and distribution networks and the assets that connect to them. To address this  
275 challenge, the NCCoE offers a risk-based approach to cybersecurity and proactive cybersecurity defense  
276 mechanisms that organizations can use to assure that information exchanges between and among DERs  
277 can be monitored, secured, and trusted.

278 The NCCoE collaborated with an Energy Sector Community of Interest that included technology and  
279 cybersecurity vendors, subject matter experts from the electric power industry, academia, and

280 government to define the project scope and cybersecurity challenges, DER use cases, data flows and  
281 information exchanges, and a reference architecture.

282 We then assembled a team of cybersecurity vendors and subject matter experts to refine the solution  
283 and build a laboratory prototype of the reference architecture. The prototype example solution uses a  
284 combination of logical and physical infrastructure at the NCCoE and on the UMD campus.

### 285 **3.1 Audience**

286 This guide is intended for individuals and organizations responsible for the safe, secure, responsive, and  
287 efficient operation and interconnection of DERs with the distribution grid. This could include distribution  
288 utilities, investor-owned utilities, municipal utilities, utility cooperatives, independent power producers,  
289 distribution and microgrid owners and operators (including their investors and insurers), DER  
290 aggregators, and DER vendors. The guide may also be of interest to anyone in industry, academia, or  
291 government who seeks general knowledge of DER cybersecurity.

### 292 **3.2 Scope**

293 This NCCoE project and reference architecture demonstrate an approach for improving the overall  
294 security of IIoT in a DER environment and address the following areas of interest:

- 295       ▪ the information exchanges between and among DER systems and distribution facilities/entities  
296       and the cybersecurity considerations involved in these interactions
- 297       ▪ the processes and cybersecurity technologies needed for trusted device identification and  
298       communication with other devices
- 299       ▪ the ability to provide malware prevention, detection, and mitigation in operating environments  
300       where information exchanges occur
- 301       ▪ the mechanisms that can be used for protecting both system and data transmission components
- 302       ▪ data-driven cybersecurity analytics to help DER owners and operators securely perform  
303       necessary tasks

### 304 **3.3 Assumptions**

305 This project is guided by the following assumptions:

- 306       ▪ The solution is being developed in a lab environment to mimic commercial- and utility-scale  
307       DERs connecting to the distribution grid. We did not interconnect with an actual distribution  
308       utility as part of the project.
- 309       ▪ An organization has access to the skills and resources necessary to implement the cybersecurity  
310       capabilities highlighted in the project.

- 311       ▪ The IIoT components and devices used in the project are trustworthy (i.e., there are no supply  
312 chain cybersecurity concerns) on initial connection to the lab environment.

### 313 3.4 Risk Assessment

314 [NIST SP 800-30 Revision 1, \*Guide for Conducting Risk Assessments\*](#), states that risk is “a measure of the  
315 extent to which an entity is threatened by a potential circumstance or event, and typically a function of:  
316 (i) the adverse impacts that would arise if the circumstance or event occurs; and (ii) the likelihood of  
317 occurrence.” The guide further defines risk assessment as “the process of identifying, estimating, and  
318 prioritizing risks to organizational operations (including mission, functions, image, reputation),  
319 organizational assets, individuals, other organizations, and the Nation, resulting from the operation of  
320 an information system. Part of risk management incorporates threat and vulnerability analyses, and  
321 considers mitigations provided by security controls planned or in place.”

322 The NCCoE recommends that any discussion of risk management, particularly at the enterprise level,  
323 begins with a comprehensive review of [NIST SP 800-37 Revision 2, \*Risk Management Framework for\*](#)  
324 [Information Systems and Organizations](#)—material that is available to the public. The [Risk Management](#)  
325 [Framework \(RMF\)](#) guidance, as a whole, proved to be invaluable in giving us a baseline to assess risks  
326 and evaluate the security characteristics of the reference architecture, example solution, and this guide.

327 We performed two types of risk assessment in this project:

- 328       ▪ Initial analysis of the risk factors based on discussions with the Energy Sector Community of  
329 Interest and key stakeholders in the electric power industry, academia, and the cybersecurity  
330 technology domain. This analysis led to creating the [Securing the Industrial Internet of Things:](#)  
331 [Cybersecurity for Distributed Energy Resources](#) project description.
- 332       ▪ Analysis of how to secure the components, connections, and information exchanges within the  
333 reference architecture and to minimize any vulnerabilities they might introduce. See [Section 5,](#)  
334 Security Characteristic Analysis.

#### 335 3.4.1 Threats

336 NIST SP 800-30 Revision 1 defines a threat as, “... any circumstance or event with the potential to  
337 adversely impact organizational operations.” For this project, threats are viewed from the standpoint of  
338 cybersecurity and the cyber events that could impact or compromise the integrity or control of DER  
339 information exchanges.

340 DERs employ industrial control systems (ICS). The Cybersecurity and Infrastructure Security Agency  
341 (CISA) ICS-Computer Emergency Readiness Team (CERT) defines cyber-threat sources to ICS as “persons  
342 who attempt unauthorized access to a control system device and/or network using a data  
343 communications pathway” [3]. CISA ICS-CERT, along with [NIST SP 800-82 Revision 2, \*Guide to Industrial\*](#)  
344 [Control Systems \(ICS\) Security](#), identifies malicious actors who may pose threats to ICS infrastructure,

345 including foreign intelligence services (i.e., national government organizations whose intelligence-  
346 gathering and espionage activities seek to harm U.S. interests), criminal groups such as organized crime  
347 groups that seek to attack for monetary gain, and hackers.

348 The Electric Power Research Institute (EPRI) outlined several potential cybersecurity threats to DERs in  
349 its December 2015 publication [Electric Sector Failure Scenarios and Impact Analyses—Version 3.0](#). EPRI’s  
350 threat events influenced the scope of this NCCoE project. Specifically, our reference architecture  
351 addresses several scenarios where a malicious actor attempts to gain access to DER systems to deploy  
352 malware, to manipulate or disrupt data and information exchanges, or to assume control of a utility or  
353 microgrid management system. These “attacks” could happen independently or together as part of a  
354 larger effort to ultimately gain control of the distribution grid or a utility’s business network. As such,  
355 our reference architecture is being built and tested to address threats to data integrity, industrial  
356 control malware protection and detection, and device and data authenticity.

### 357 3.4.2 Vulnerabilities

358 NIST defines a vulnerability as a “weakness in an information system, system security procedures,  
359 internal controls, or implementation that could be exploited or triggered by a threat source.” A  
360 vulnerability may exist inherently within a device or within the design, operation, installation, and  
361 architecture of a system. This project does not specifically address vulnerabilities related to devices,  
362 software, hardware, or networks used in the example solution or to the cybersecurity policies that a  
363 distribution grid operator has in place. We encourage a consistent and comprehensive approach to  
364 detecting vulnerabilities. While we understand the constraints of scanning and patching industrial  
365 networks and devices, we also believe that overlooking known vulnerabilities increases cybersecurity  
366 risk. The chances of a malicious actor gaining unauthorized access increase if an exploitable vulnerability  
367 is left unaddressed. NIST SP 800-82 categorizes ICS vulnerabilities into the following categories with  
368 examples:

- 369       ▪ **policy and procedure**—incomplete, inappropriate, or nonexistent security policy, including its  
370       documentation, implementation guides (e.g., procedures), and enforcement
- 371       ▪ **architecture and design**—design flaws, development flaws, poor administration, and connections  
372       with other systems and networks
- 373       ▪ **configuration and maintenance**—misconfiguration and poor maintenance
- 374       ▪ **physical**—lack of or improper physical access control, malfunctioning equipment
- 375       ▪ **software development**—improper data validation, security capabilities not enabled, inadequate  
376       authentication privileges
- 377       ▪ **communication and network**—nonexistent authentication, insecure protocols, improper firewall  
378       configuration

379 Performing vulnerability management and remediation tasks can provide the DER or utility operator at  
380 least some level of assurance that they have reduced or mitigated the possibility of an exploit.  
381 Vulnerabilities will vary from network to network, and even those specific to particular devices may vary  
382 depending on the disposition or deployment of that device in an operating environment.

383 Finally, knowledge of deployed assets is paramount in securing an organization's ICS infrastructure and  
384 mitigating risks associated with asset-based vulnerabilities. [NIST Special Publication 1800-23, Energy  
385 Sector Asset Management](#), describes a solution for monitoring and managing deployed OT assets.

### 386 3.4.3 Risk

387 Risk management is the ongoing process of identifying, assessing, and responding to risk as it relates to  
388 an organization's mission objectives. To manage risk, organizations should understand the likelihood  
389 that an event will occur and its potential impacts. An organization should also consider statutory and  
390 policy requirements that may influence or inform cybersecurity decisions.

391 Information system-related security risks are those risks that arise from loss of confidentiality, integrity,  
392 or availability of information or information systems and that reflect potential adverse impacts to  
393 organizational operations (including mission, functions, image, or reputation), organizational assets,  
394 individuals, other organizations, and the nation. For the energy sector, a primary risk to OT networks is  
395 the loss of power production and distribution assets. As described in the threats section earlier, loss in  
396 the trustworthiness of the data, loss of control of the industrial network, or introduction of malware into  
397 OT can have serious consequences.

398 This practice guide is informed by cybersecurity risk management processes. We provide part of the  
399 information needed to make informed decisions—based on business needs and risk assessments—to  
400 select and prioritize cybersecurity activities that are deemed necessary by your organization.

### 401 3.4.4 Security Control Map and Technologies

402 Table 3-1 maps the security characteristics of our reference architecture to the NIST Cybersecurity  
403 Framework [4] security Functions, Categories, and Subcategories that it supports. The technologies used  
404 in this project are mapped to the Cybersecurity Framework Subcategories they support. We selected the  
405 Subcategories that address the threats, vulnerabilities, and risks discussed above. Your organization can  
406 use Table 3-1 to identify the corresponding NIST SP 800-53 Rev 5 controls necessary to achieve the  
407 desired outcomes. While our reference architecture focuses on the Protect and Detect Functions of the  
408 Cybersecurity Framework, there are more Functions, Categories, and Subcategories in the framework  
409 than appear here. Your organization should select the Cybersecurity Framework Subcategories and  
410 controls that help mitigate your business-specific cybersecurity risks.

411 Table 3-1 Security Characteristics and Controls Mapping—NIST Cybersecurity Framework

Function	Category	Subcategory	NIST 800-53, Revision 5 Control(s)	Product by Function in Project
PROTECT (PR)	<b>Identity Management, Authentication, and Access Control (PR.AC):</b> Access to physical and logical assets and associated facilities is limited to authorized users, processes, and devices and is managed consistent with the assessed risk of unauthorized access to authorized activities and transactions.	<b>PR.AC-1:</b> Identities and credentials are issued, managed, verified, revoked, and audited for authorized devices, users, and processes.	IA-1, IA-2, IA-3, IA-4, IA-5, IA-7, IA-8, IA-9, IA-10, IA-11, IA-12	<p><b>Cisco Identity Services Engine (ISE)</b> provides identity and access management capabilities; determines whether users are accessing the network on an authorized, policy-compliant device, and allows access to services based on associated policy.</p> <p><b>TDi ConsoleWorks</b> manages the privileged access credentials for systems. These credentials are never seen or used directly by privileged users.</p> <p><b>Xage Security Fabric</b> manages identities and credentials for users, applications, and devices. .</p>
		<b>PR.AC-3:</b> Remote access is managed.	AC-1, AC-17, AC-19, AC-20, SC-15	<p><b>BlackRidge Gateway</b> provides first-packet authentication of incoming transmission control protocol (TCP) connections and enforces network access control policy, preventing unauthorized TCP connections through the gateway to protected devices and services.</p>

Function	Category	Subcategory	NIST 800-53, Revision 5 Control(s)	Product by Function in Project
		<b>PR.AC-4:</b> Access permissions and authorizations are managed, incorporating the principles of least privilege and separation of duties.	AC-1, AC-2, AC-3, AC-5, AC-6, AC-14, AC-16, AC-24	<b>Xage Security Fabric</b> provides policy creation for fine-grained, multiparty access control and authentication of all the human, machine, and application/hardware assets within the utility.
				<b>Anterix</b> provides a wireless broadband network capability for the campus microgrid over a long-term evolution (LTE) network. The solution includes LTE’s extensive authentication and access control features for communications that traverse the network.
				<b>Cisco ISE</b> provides identity and access management capabilities.
				<b>TDi Technologies ConsoleWorks</b> manages privileged user access permissions. Privileged users authenticate to ConsoleWorks by either using local authentication capabilities or leveraging external authentication technologies and are then given access to systems they are supposed to manage.

Function	Category	Subcategory	NIST 800-53, Revision 5 Control(s)	Product by Function in Project
				<p><b>Xage Security Fabric</b> provides policy creation capabilities for fine-grained multiparty access control and authentication of all the human, machine, and application/hardware assets within the utility. Fine-grained access control policies are created, and authentication is enforced for every asset. This includes authentication and authorization of peer-to-peer connections between various control systems within utility systems. Failed access requests, rogue device detection, and OT device tampering are logged.</p>
				<p><b>BlackRidge Transport Access Control (TAC) Gateway</b> provides first-packet authentication of incoming TCP connections and enforces network access control policy, preventing unauthorized TCP connections through the gateway to protected devices and services.</p>
		<p><b>PR.AC-5:</b> Network integrity is protected (e.g., network segregation, network segmentation).</p>	<p>AC-4, AC-10, SC-7, SC-10, SC-20</p>	<p><b>Xage Security Fabric</b> provides fine-grained access control policies and authentication enforcement for every asset. This includes authentication and authorization of peer-to-peer connections between various control systems within the utility and between the utility and microgrid operators.</p>

Function	Category	Subcategory	NIST 800-53, Revision 5 Control(s)	Product by Function in Project
				<b>Spherical Analytics Immutably</b> provides data-integrity and availability technologies that protect data at rest or in transit, detects data-integrity violations, and ensures data authenticity.
	<b>Data Security (PR.DS):</b> Information and records (data) are managed consistent with the organization’s risk strategy to protect the confidentiality, integrity, and availability of information.	<b>PR.DS-1:</b> Data at rest is protected.	MP-2, MP-3, MP-4, MP-5, MP-6, MP-7, MP-8, SC-28	<b>Anterix</b> provides an LTE-based broadband network that includes LTE’s data encryption and integrity features for data in transit.
		<b>PR.DS-2:</b> Data in transit is protected.	SC-8, SC-11	<b>Spherical Analytics Immutably</b> provides data-integrity technologies that protect data at rest or in transit, detects data-integrity violations, and ensures data authenticity.

Function	Category	Subcategory	NIST 800-53, Revision 5 Control(s)	Product by Function in Project
		<b>PR.DS-6:</b> Integrity-checking mechanisms are used to verify software, firmware, and information integrity.	SI-7, SI-10	<b>Spherical Analytics Immutably</b> provides data-integrity technologies that protect data at rest or in transit, detect data-integrity violations, and ensure data authenticity.
				<b>Sumo Logic Enterprise</b> provides protections to ensure data encryption at rest and in transit. Logs are immutable.
				<b>Xage Security Fabric</b> provides data integrity via fingerprinting for every interaction within the campus microgrid network. In addition, data authenticity to and from both the DER microgrid and the utility network is guaranteed.
				<b>Cisco Cyber Vision</b> learns the expected traffic flows and establishes those as the baseline.
				<b>TDi Technologies ConsoleWorks</b> monitors for assets that have been newly discovered on a network and can leverage that information to create new devices in ConsoleWorks.
<b>DETECT (DE)</b>	<b>Anomalies and Events (DE.AE):</b> Anomalous activity is detected, and the potential impact of events is understood.	<b>DE.AE-1:</b> A baseline of network operations and expected data flows for users and systems is established and managed.	AC-4, CA-3, CM-2, SC-16, SI-4	<p><b>Radiflow iSID</b> learns the expected traffic flows and establishes those as the baseline.</p> <p><b>TDi Technologies ConsoleWorks</b> monitors for assets that have been newly discovered on a network and can leverage that information to create new devices in ConsoleWorks.</p>

Function	Category	Subcategory	NIST 800-53, Revision 5 Control(s)	Product by Function in Project
				<b>Cisco Cyber Vision</b> provides network anomaly detection for operational technology traffic.
		<b>DE.AE-2:</b> Detected events are analyzed to understand attack targets and methods.	AU-6, CA-7, RA-5, IR-4, SI-4	<p><b>Radiflow iSID</b> provides operational technology network monitoring to detect potentially malicious activity.</p> <p><b>Sumo Logic Enterprise</b> provides analysis and visualization capabilities to collect and process monitoring data from communications, management systems, and control systems to detect anomalies and identify anomalies that represent potential malicious activity via outlier detection. Behavioral monitoring capabilities measure behavioral characteristics of the management and control systems. SC-44, SI-3, SI-4, SI-8	<p><b>Radiflow iSID</b> provides operational technology network monitoring to detect potentially malicious activity.</p> <p><b>Spherical Analytics</b> provides graph analytics, machine learning, behavioral monitoring, and predictive analytics that aid in detecting malware and data-integrity violations.</p> <p><b>Cisco Cyber Vision</b> provides network anomaly detection for operational technology traffic.</p>
		<b>DE.CM-7:</b> Monitoring for unauthorized personnel, connections, devices, and software is performed.	AU-12, CA-7, CM-3, CM-8, PE-6, PE-20, SI-4	<p><b>Radiflow iSID</b> provides operational technology network monitoring to detect potentially malicious activity.</p>

412 **3.4.5 Cybersecurity Workforce Considerations**

413 Table 3-2 identifies the cybersecurity work roles that most closely align with the Cybersecurity Frame-  
 414 work security Categories and Subcategories demonstrated in our reference architecture. The work roles  
 415 are based on the [National Initiative for Cybersecurity Education](#) (NICE) Workforce Framework for Cyber-  
 416 security (NICE Framework). Note that the work roles shown may apply to more than one NIST Cyberse-  
 417 curity Framework Category.

418  
 419 More information about NICE and other work roles can be found in [NIST SP 800-181 Revision 1, Work-](#)  
 420 [force Framework for Cybersecurity \(NICE Framework\)](#).

421 **Table 3-2 Cybersecurity Work Roles Aligned to Reference Architecture**

NICE Work Role ID	NICE Work Role	Work Role Description	Category	Specialty Area	Cybersecurity Framework Subcategory Mapping
OM-ADM-001	System Administrator	Responsible for setting up and maintaining a system or specific components of a system (e.g., installing, configuring, and updating hardware and software; establishing and managing user accounts; overseeing or conducting backup and recovery tasks; implementing operational and technical security controls; and adhering to organizational security policies and procedures).	Operate and Maintain	Systems Administration	PR.AC-1, PR.AC-3, PR.AC-4
SP-SYS-001	Information Systems Security Developer	Designs, develops, tests, and evaluates information system security throughout the systems development life cycle.	Securely Provision	Systems Development	PR.AC-5, PR.DS-1, PR.DS-2, PR.DS-6, DE.AE-1

## 422 4 Architecture

423 The IEEE standard 1547-2018, *IEEE Standard for Interconnection and Interoperability of Distributed*  
424 *Energy Resources with Associated Electric Power Systems Interfaces* requires that a DER have a  
425 communication interface to exchange monitoring and control information with the area electric power  
426 systems (EPS) operator. The standard defines the minimum set of information that the DER must be able  
427 to exchange with the area EPS operator. This architecture addresses the security of these information  
428 exchanges.

429 This architecture helps ensure that both the DER operator and the local utility have confidence that the  
430 information exchanges are legitimate. This publication refers to the area EPS operator as a local utility.

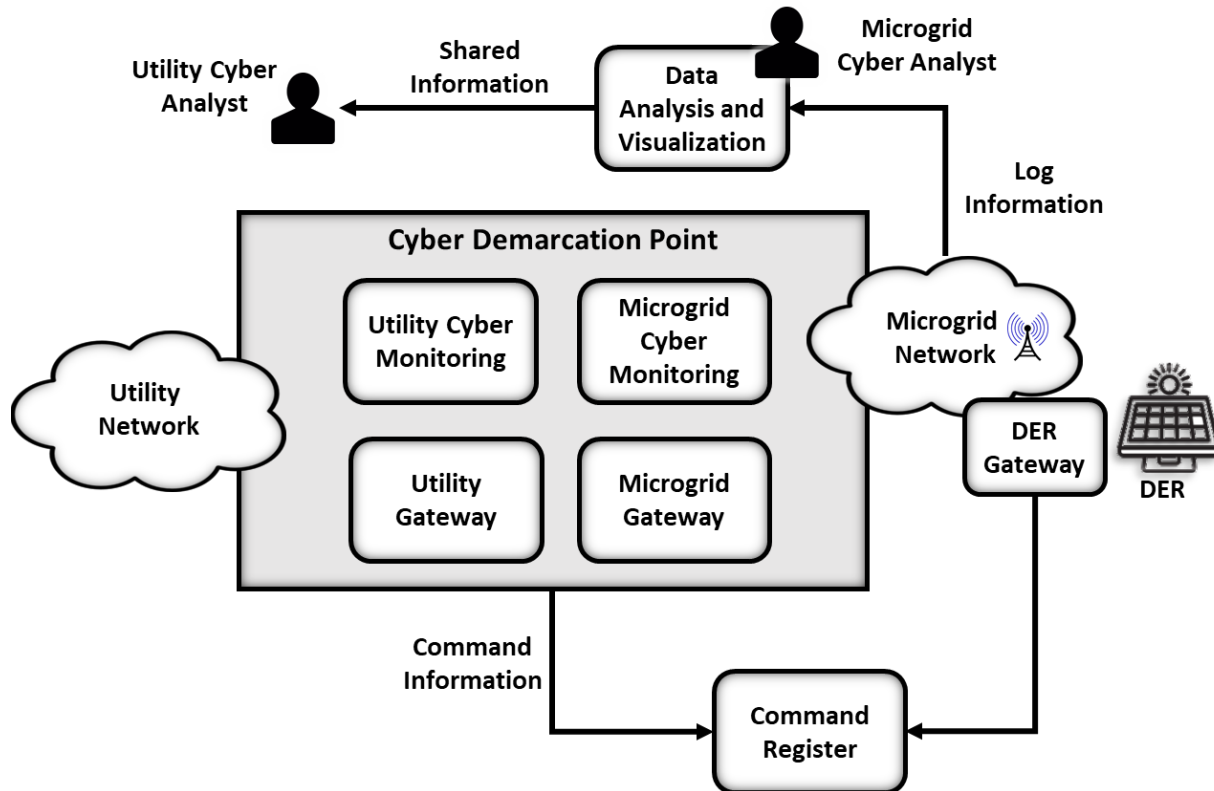

### 431 4.1 Architecture Description

432 The project reference architecture demonstrates the following capabilities to protect, monitor, and  
433 audit DER information exchanges.

- 434     ▪ All information exchanges are by and between authenticated and authorized entities.
- 435     ▪ The networks used to exchange information are monitored, and suspicious activity is detected  
436         and reported.
- 437     ▪ A distributed ledger of information exchanges is maintained by a third party to allow both DER  
438         operators and the utility to independently verify the information exchanges.
- 439     ▪ A DER operator log collection and analysis capability provide controlled results sharing with the  
440         utility and other DER operators.

441 Figure 1 depicts the reference architecture used to protect information exchanges.

442 Figure 1 Reference Architecture

443 Figure 1 shows the elements of the reference architecture. The core element is the cyber demarcation  
 444 point. The cyber demarcation point separates a utility network and a microgrid network—a network  
 445 that is owned and controlled by a DER operator. The cyber demarcation point is responsible for  
 446 independently enforcing two distinct security policies—the utility’s security policy and the microgrid  
 447 owner’s security policy. There is a cyber demarcation point at each DER operator site. It contains the  
 448 following:

- 449     ▪ The **utility gateway** component implements the utility’s access policy. It verifies the identity of  
 450 any entity on the utility network attempting to exchange information with microgrid-based DERs  
 451 and allows access based on the utility’s defined access policy. This gateway is owned, managed,  
 452 and operated by the utility. We assume all information exchanges originate on the utility  
 453 network via a request from the utility to a DER on the microgrid network.
- 454     ▪ The **microgrid gateway** component implements the microgrid access policy. It receives  
 455 information requests from the utility gateway and passes authorized requests into the microgrid  
 456 network. This gateway is owned, managed, and operated by the microgrid operator.

- 457       ▪ The **utility cyber monitoring** component examines network and application traffic on the utility  
458       network and alerts utility cybersecurity personnel if suspicious activity is detected. This  
459       component is owned, managed, and operated by the utility.
- 460       ▪ The **microgrid cyber monitoring** component examines network and application traffic on the  
461       microgrid network and alerts microgrid cybersecurity personnel if suspicious activity is detected.  
462       This component is owned, managed, and operated by the microgrid operator.

463 This architecture allows both the utility and the microgrid operator to control access to DERs on the  
464 microgrid. Both must agree to allow access to a DER. Similarly, both the utility and the microgrid  
465 operator can detect suspicious activity. There is no requirement for the utility or the microgrid operator  
466 to use the same products to implement these capabilities. There is a potential security benefit in each  
467 organization choosing different products, which provides a degree of diversity in an implementation.  
468 The selected products, however, must be able to exchange information via defined protocols. IEEE 1547-  
469 2018 identifies three TCP/internet protocol-based protocols that may be used for information  
470 exchanges.

471 The microgrid network in Figure 1 connects to the customer-owned DER devices. It may be a  
472 combination of wired and wireless network segments. A DER gateway protects each DER device. This  
473 gateway controls access to the DER device. Using a device gateway allows the microgrid gateway to  
474 implement coarse-grained policies that are not device specific. The microgrid gateway can allow a  
475 request independent of device. The device gateways can then implement fine-grained policies that are  
476 device specific. This allows the microgrid gateway policies to be independent of the specific devices  
477 currently accessible on the microgrid network. Note that the reference architecture allows but does not  
478 require the microgrid gateway policy to be independent of the specific devices on the microgrid  
479 network.

480 The reference architecture assumes the DER microgrid is neither owned nor operated by the utility. The  
481 microgrid operator and the utility may both independently collect audit trails that record information  
482 exchanges. As such, there is no single authoritative record of these exchanges. A complete audit trail  
483 would have to be constructed by combining audit records from the utility and the microgrid operator.

484 Each gateway in the reference architecture records the information exchanges it handles in a command  
485 register. The command register is a distributed ledger operated by a trusted third party. It provides an  
486 accurate, immutable record of all information exchanges that may be reviewed by both the utility and  
487 the microgrid operator. The ledger provides an authoritative source for determining who said what to  
488 whom and when and is a complete audit trail of information exchanges.

489 Last, the reference architecture provides collection and analysis of the log files from systems on the  
490 microgrid network and sharing select analysis results with the utility. This provides a degree of shared  
491 situational awareness. Log information is collected from source systems and sent to a cloud analytics  
492 platform. The microgrid operator's cyber defense analysts have full access to all the log information and  
493 analysis results. The microgrid operator may choose to share select results with the utility. It is easier to

494 realize this selective sharing by using a cloud platform than it would be by using an on-premises analysis  
495 platform. The cloud analytics platform can also enable select information sharing between and among  
496 microgrid operators.

## 497 4.2 Example Solution Description

498 A laboratory prototype instance of the reference architecture, called an “example solution,” is being  
499 constructed to verify the design. The example solution consists of a combination of logical and physical  
500 infrastructure at the NCCoE and on the UMD campus. This preliminary draft describes the intended  
501 implementation of the example solution. At the time of writing this preliminary draft, the design is not  
502 fully implemented, and some details may change.

503 The utility network and the cyber demarcation point are represented in the example solution by virtual  
504 infrastructure in the NCCoE lab.

505 The microgrid network is represented by three distinct components: a virtual network in the NCCoE lab,  
506 the UMD campus network, and an LTE network installed on the UMD campus.

### 507 4.2.1 Cyber Demarcation Point

508 The components of the cyber demarcation point were each implemented using different products.  
509 Therefore, the utility and microgrid components are described separately. Figure 2 illustrates the  
510 products and services used to implement the utility components of the cyber demarcation point. Figure  
511 3 illustrates the products and services used to implement the microgrid operator components of the  
512 cyber demarcation point.

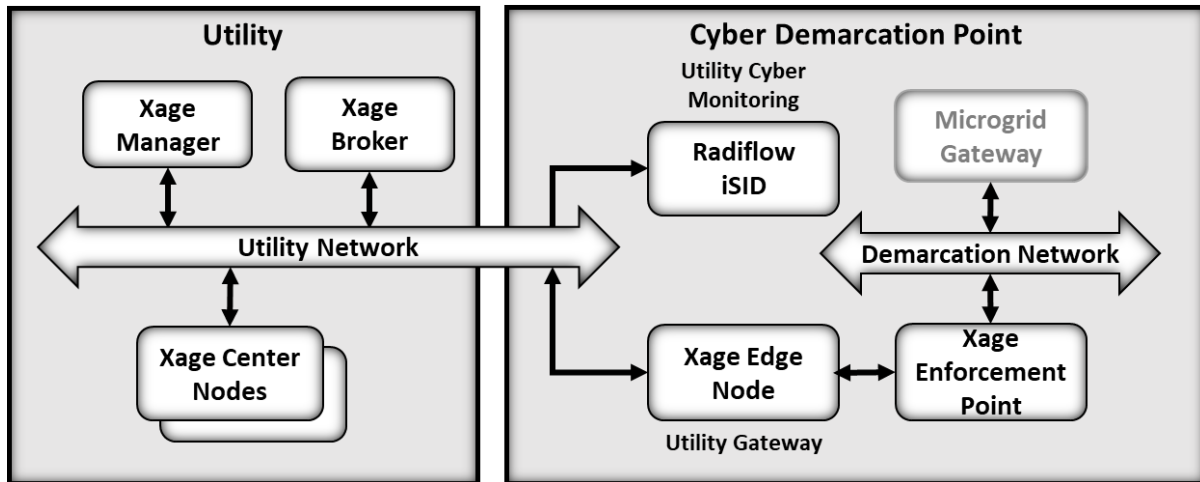

#### 513 4.2.1.1 Utility Gateway and Cyber Monitoring

514 We used the Xage Security Fabric for the utility gateway component. This product is composed of five  
515 services:

- 516     ▪ The Xage Manager configures users, devices, and access policies. The policies are then sent to  
517     Xage Broker. There is one Xage Manager operated by the utility and used to configure security  
518     policies for access to all DERs.
- 519     ▪ The Xage Broker is the authoritative source for security policy information. Xage Broker can  
520     store the policy locally or use enterprise services such as a lightweight directory access protocol  
521     directory or Microsoft Active Directory. In the NCCoE example solution, all information is stored  
522     locally in the broker. There is one Xage Broker operated by the utility to store and distribute  
523     access policies for all DERs.
- 524     ▪ The Xage Center Nodes use a distributed ledger to provide a geographically distributed  
525     information store that is tamperproof. The Xage Broker distributes policy information to the  
526     Xage Center Nodes. This distributed information store provides policy information for the Xage  
527     Edge Nodes.

- 528       ▪ A Xage Edge Node is in the cyber demarcation point at each microgrid operator site. The Xage  
529       Edge Node retrieves security information for its site from the Xage Center Nodes and stores it  
530       locally within the cyber demarcation point.
- 531       ▪ The Xage Enforcement Point (XEP) in the cyber demarcation point uses the security information  
532       to allow or deny access to DERs on the microgrid network.

533 **Figure 2 Utility Gateway and Cyber Monitoring**

534

535 The utility uses the Xage Manager to configure its security policy for each DER site. These policies are  
536 distributed by the Xage Broker to the Xage Center Nodes. The Xage Edge Node at a DER site retrieves its  
537 security information from a Xage Center Node and provides that security information to the DER site’s  
538 XEP. When the utility exchanges information with a DER site, the XEP verifies the exchange by using the  
539 security information from its Xage Edge Node and allows authorized exchanges to pass to the microgrid  
540 gateway and ultimately to the intended DER device.

541 The combination of the Xage Center Nodes and Xage Edge Node storage of security information  
542 provides redundancy that ensures that the security information to authorize information exchanges is  
543 always available. Using a distributed ledger by the Xage Center Nodes ensures the integrity of the stored  
544 security information.

545 We used Radiflow iSID for the utility cyber monitoring component. Radiflow iSID is a passive monitoring,  
546 analysis, and detection platform that can be provided as either a physical or logical appliance. iSID learns  
547 the basic topology and behavior of the industrial control devices on the networks that it monitors. A  
548 typical deployment places an iSID appliance at a central location on the utility network and deploys iSAP  
549 Smart Collectors to each cyber demarcation point. To simplify the NCCoE lab example solution, a single  
550 virtual appliance was deployed that acts as both the analysis and detection engine and the network  
551 sensor.

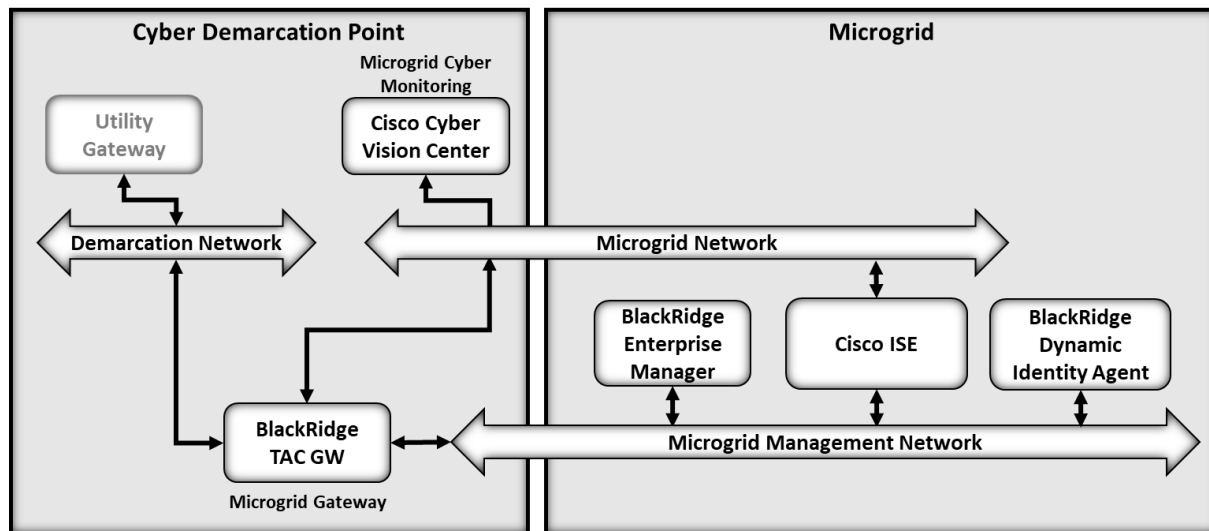

552 iSID allows the utility to see all devices connected to the utility network, detect anomalous behavior on  
 553 the network, and detect policy violations in communications occurring over the network with DERs. This  
 554 information is made available to utility cyber analysts through a collection of dashboards that provide  
 555 both high-level and drill-down views and visualization of the monitoring and alert data.

556 In the NCCoE example solution, we placed iSID on the utility network in the cyber demarcation point.  
 557 This placement provides information about all of the activity across the utility network. A sensor could  
 558 also be placed on the demarcation network of the cyber demarcation point to provide insight into  
 559 network traffic traversing the utility gateway.

560 *4.2.1.2 Microgrid Gateway and Cyber Monitoring*

561 We implemented the microgrid gateway by using BlackRidge Technology’s TAC product. The product  
 562 consists of two services: the BlackRidge Enterprise Manager and the BlackRidge TAC Gateway (GW). The  
 563 gateways control access based on the identity of the entity attempting to communicate through the  
 564 gateway. An identity token is inserted into the header of the first packet sent to open a TCP connection.  
 565 If the gateway recognizes the identity and the identity is authorized to send information through the  
 566 gateway, the gateway accepts the connection request. If the identity is not recognized or is not  
 567 authorized, the connection request is ignored. To the requester, it appears that there is no device at the  
 568 address to which the request was directed.

569 **Figure 3 Microgrid Gateway and Cyber Monitoring**

570  
 571 A request from the utility gateway entering the microgrid through the cyber demarcation point has an  
 572 identity token assigned to it by the BlackRidge TAC GW implementing the microgrid gateway. Identities  
 573 within the microgrid are managed by the Cisco ISE. The BlackRidge Dynamic Identity Agent provides an  
 574 interface between Cisco ISE and the BlackRidge Enterprise Manager. Via this interface, the Enterprise

575 Manager can determine identity and access information to configure the TAC GW implementing the  
576 microgrid gateway.

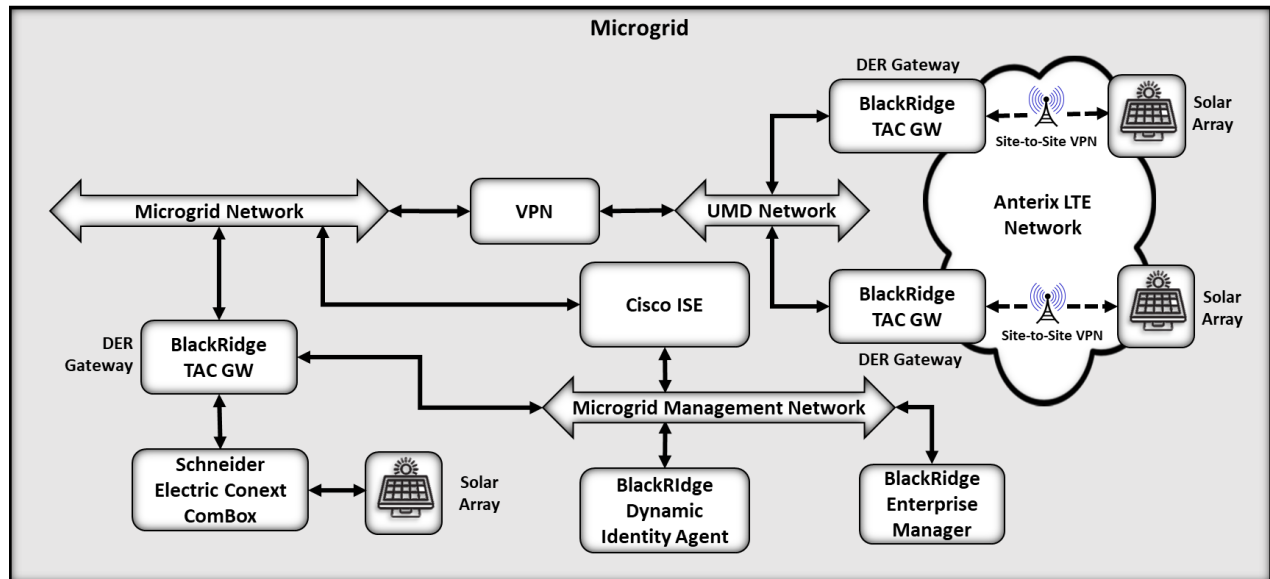

577 We implemented the microgrid cyber monitoring component by using Cisco Cyber Vision. Cisco Cyber  
578 Vision is a passive monitoring, analysis, and detection platform that can be provided as either a physical  
579 or logical appliance. Cyber Vision learns the basic topology and behavior of the industrial control devices  
580 on the networks that it monitors. A typical deployment places a Cyber Vision appliance at a central  
581 location on the microgrid network and deploys Cyber Vision sensors to various locations of interest on  
582 the microgrid network. In the example solution, for example, we could have placed sensors at UMD and  
583 in the NCCoE lab. To simplify the NCCoE lab example solution, a single virtual appliance was deployed in  
584 the NCCoE lab that acts as both the analysis and detection engine and the network sensor.

585 Cyber Vision allows the microgrid operator to see all devices connected to the microgrid network, detect  
586 anomalous behavior on the network, and detect policy violations in communications occurring over the  
587 network with DERs. This information is made available to microgrid cyber analysts through a collection  
588 of dashboards that provide both high-level and drill-down views and visualization of the monitoring and  
589 alert data.

590 In the NCCoE example solution, Cyber Vision was placed on the microgrid network. This placement  
591 provides information about all the activity on the microgrid network, including traffic entering the  
592 network from the cyber demarcation point. A sensor could also be placed on the demarcation network  
593 to observe traffic entering the microgrid gateway from the utility network to provide insight into  
594 network traffic traversing the microgrid gateway.

## 595 4.2.2 Microgrid Network, DER Gateway, and DER

596 Figure 4 Microgrid Network

597 We implemented the microgrid network as a combination of a virtual network in the NCCoE lab, a wired  
 598 network in the NCCoE lab, a wired network on the UMD campus, and an LTE network. The virtual  
 599 network in the NCCoE lab is connected via a physical network switch to a physical BlackRidge TAC GW.  
 600 This BlackRidge TAC GW controls access to a Schneider Electric Conext ComBox. The ComBox is the  
 601 communication interface to an inverter connected to four solar panels in the NCCoE lab. Communication  
 602 with the ComBox is via SunSpec Modbus over TCP.

603 A virtual private network (VPN) using pfSense firewalls connects the virtual network in the NCCoE lab to  
 604 the UMD campus network. Two virtual BlackRidge TAC GWs are installed at UMD to control access to  
 605 two solar arrays at UMD. The UMD campus network does not reach the two parking garages where the  
 606 solar arrays are installed. An Anterix LTE network connects each of the parking garage solar arrays to the  
 607 UMD campus network. Point-to-point VPNs over the LTE network connect each TAC GW to a solar array.  
 608 Communication with the solar arrays uses Modbus over TCP. Figure 4 shows how these products and  
 609 services are assembled into an example of the microgrid network element in the reference architecture.

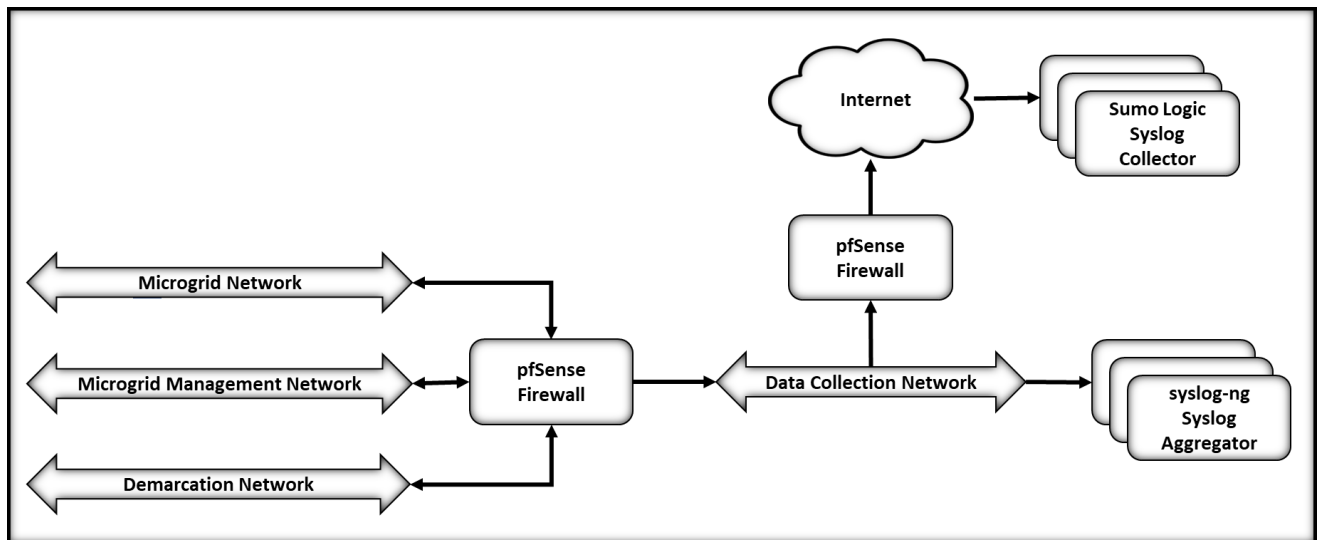

610 A Modbus command from the utility destined for either the UMD solar arrays or the NCCoE lab solar  
 611 array enters the microgrid network through the cyber demarcation point. The BlackRidge TAC GW in the  
 612 cyber demarcation point assigns an identity to the command and connects it to the appropriate DER  
 613 gateway. That connection will succeed only if the BlackRidge TAC Gateway, used as the DER gateway,  
 614 recognizes the identity assigned in the cyber demarcation point. If there is no assigned identity, or if the

615 identity is not authorized to communicate with the solar array, no TCP connection will be made to the  
 616 DER gateway.

617 As described for the microgrid gateway in the cyber demarcation point, the BlackRidge Dynamic Identity  
 618 Agent provides an interface between Cisco ISE, which manages identities and access policy, and the  
 619 BlackRidge Enterprise Manager, which configures the TAC GWs implementing the DER gateways.

### 620 4.2.3 Data Analysis and Visualization

621 **Figure 5 Data Analysis and Visualization**

622 We plan to implement data analysis and visualization using Sumo Logic’s cloud analytics platform as  
 623 shown in Figure 5. We will collect syslog data from products and services on the microgrid network, the  
 624 microgrid management network, and the demarcation network. This log information will be uploaded to  
 625 Sumo Logic for analysis and presentation of results via a dashboard.

626 Three syslog aggregators, implemented using syslog-ng, will be placed on a dedicated data collection  
 627 network. Syslog data sources on the two microgrid networks and the demarcation network will send  
 628 their syslog data to one of the three aggregators. Each of these aggregators in turn will forward the  
 629 collected syslog data to syslog collectors at Sumo Logic that will ingest the data into the analytics  
 630 platform.

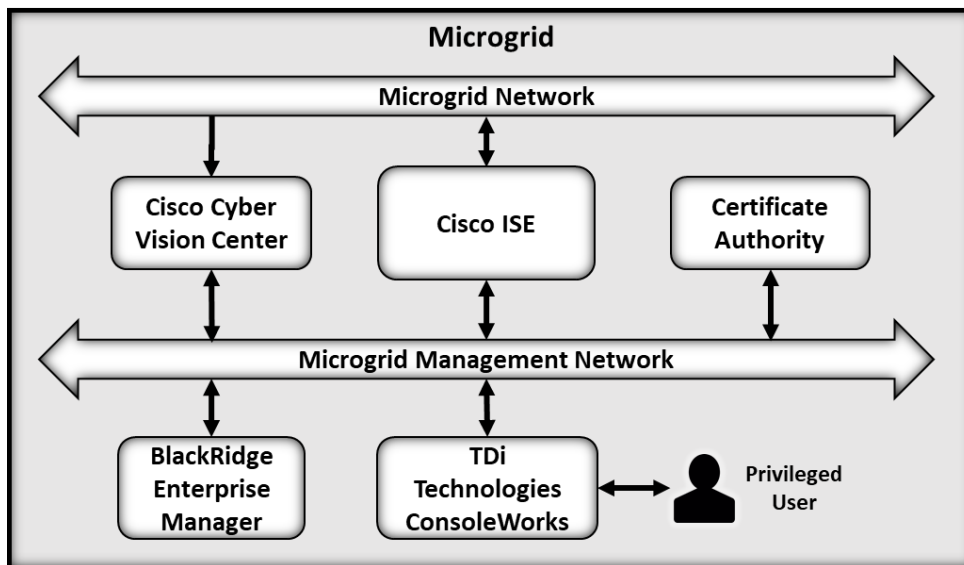

631 The pfSense firewalls will be used to segregate the data collection network from the microgrid and  
 632 demarcation point networks and to control connections between the syslog aggregators and the  
 633 internet. While not shown in Figure 5, the NIST and NCCoE corporate firewalls and network monitoring  
 634 tools will also protect the connection from the log collection network to the internet.

658 Privileged users manage the configuration of infrastructure and security devices to determine how the  
 659 devices function and what operations they will allow. In the example solutions, privileged users must  
 660 configure user, create and manage user credentials, manage user access permissions, determine alert  
 661 thresholds, and determine what is captured in audit trails.

662 Cisco ISE, Cisco Cyber Vision, and BlackRidge Enterprise Manager have dedicated interfaces for  
 663 configuration and management. Additionally, the BlackRidge Enterprise Manager uses a certificate  
 664 authority for configuring the BlackRidge TAC Gateways. The certificate authority does not need to be  
 665 accessible from the microgrid or cyber demarcation point. These dedicated management interfaces and  
 666 the certificate authority are connected to a dedicated microgrid management network as shown in  
 667 Figure 7.

668 **Figure 7 Microgrid Management Network**

669 Privileged users do not have direct access to the microgrid management network, the products’  
 670 dedicated management interfaces, or privileged access credentials for the products. TDi Technologies  
 671 ConsoleWorks provides privileged user management. ConsoleWorks maintains the credentials used to  
 672 access the dedicated management interfaces. Privileged users have credentials that allow them to  
 673 access ConsoleWorks. ConsoleWorks uses “user profiles” to define the management interfaces that  
 674 each privileged user can access and the credentials used to access that interface. ConsoleWorks  
 675 authenticates authorized user to product management interfaces and records all privileged user actions  
 676 in an audit trail.

677 Additional information about privileged user management can be found in NIST [SP 1800-18, Privileged](#)  
 678 [Account Management for the Financial Services Sector](#). Although written for the financial sector, this  
 679 guidance is applicable to other environments.

## 680 5 Security Characteristic Analysis

681 This section discusses the results of a comprehensive security evaluation of the reference architecture  
682 shown in Figure 1 and how it supports the Cybersecurity Framework Subcategories that we identified  
683 and mapped in Table 3-1. The purpose of the security characteristic analysis is to understand the extent  
684 to which the project example solution meets its objective of demonstrating that information exchanges  
685 among DERs and electric distribution grid operations can be monitored and protected from certain  
686 cybersecurity compromises. In addition, it seeks to understand the security benefits and drawbacks of  
687 the example solution.

### 688 5.1 Assumptions and Limitations

689 The security characteristic analysis has the following limitations:

- 690     ▪ The analysis is not a comprehensive test of all security components nor a red-team exercise.
- 691     ▪ The analysis cannot identify all weaknesses.
- 692     ▪ The analysis does not include the lab infrastructure. We assume that the IT infrastructure used  
693 in the example solution is configured securely and properly managed. Testing this infrastructure  
694 would reveal only weaknesses in implementation that would not be relevant to those adopting  
695 this reference architecture.
- 696     ▪ Because this is a preliminary draft, testing the example solution is not complete. The content  
697 provided in this section is preliminary and incomplete.
- 698     ▪ The analysis considers only those product capabilities explicitly used in the example solution.  
699 Products may have additional capabilities that are not considered.
- 700     ▪ The products used to implement the utility, microgrid, and DER gateways use identity to grant  
701 or allow access. The gateways are not firewalls and do not provide network protocol-level  
702 access control.
- 703     ▪ While identities are used to control access, identity and access management technologies and  
704 processes are not addressed in the reference architecture or the example solution. See [NIST SP  
705 1800-2, Identity and Access Management for Electric Utilities](#), for more information.
- 706     ▪ The example solution includes a limited privileged user management capability. [NIST SP 1800-  
707 18, Privileged Account Management for the Financial Services Sector](#), provides additional  
708 guidance on managing privileged user access.

### 709 5.2 Example Solution Testing

710 Example solution testing verifies that the products we integrated in the lab environment work together  
711 as intended. For this project, we designed six test scenarios that are defined in Table 5-1 through Table  
712 5-6.

713 **5.2.1 Test Scenario 1: Communication Between the Utility and a DER Is Secure**

714 This test case will verify that authenticated and authorized systems on the utility network can  
 715 communicate with a DER connected to the microgrid network.

716 **Table 5-1 Test Procedures: Communication Between the Utility and a DER Is Secure**

Procedure	<ul style="list-style-type: none"> <li>▪ Within the NCCoE lab (utility network), the utility can access the lab’s solar array (DER) through the cyber demarcation point; only authenticated and authorized users are given access.</li> <li>▪ At UMD over the LTE network (microgrid network), the utility can access the UMD DERs through the cyber demarcation point; only authenticated and authorized users are given access.</li> </ul>
Architectural Requirements	<ul style="list-style-type: none"> <li>▪ Within the NCCoE lab, identity-based access management allows authenticated and authorized users.</li> <li>▪ At UMD, the LTE network has access to DERs connected to the microgrid network, and data-integrity analytics detect integrity violations and ensure data authenticity.</li> </ul>
Capabilities/ Requirements	<ul style="list-style-type: none"> <li>▪ LTE connectivity with embedded encryption through LTE point-to-point VPN</li> <li>▪ Identity engine manages and distributes authenticated and authorized identities.</li> </ul>
Expected Results	<ul style="list-style-type: none"> <li>▪ Devices and users with proper authentication and authorization can communicate between the utility and the DER.</li> <li>▪ Devices and users without proper authentication and/or authorization are unable to communicate between the utility and the DER.</li> </ul>
Actual Results	<ul style="list-style-type: none"> <li>▪ to be determined</li> </ul>
Overall Results	<ul style="list-style-type: none"> <li>▪ to be determined</li> </ul>

717 **5.2.2 Test Scenario 2: Integrity of Command Register Data and Communication Is**  
 718 **Verified**

719 This test case will verify data providence and integrity across the system for commands being exchanged  
 720 between the utility and the DER microgrid.

721 **Table 5-2 Test Procedure: Integrity of Command Register Data and Communication Is Verified**

Procedure	<ul style="list-style-type: none"> <li>▪ Communication through the cyber demarcation point is captured in the command register.</li> <li>▪ The utility and the microgrid operator can verify communication through the cyber demarcation point.</li> <li>▪ Devices along the communication path store commands in a distributed ledger.</li> </ul>
Architectural Requirements	<p>Within the NCCoE lab’s utility network, the microgrid network, and at UMD over the LTE network:</p> <ul style="list-style-type: none"> <li>▪ Devices can generate audit trails for all privileged user activities.</li> <li>▪ An audit trail of information exchanged between devices is provided.</li> <li>▪ Audit logs are delivered to the command register.</li> </ul>
Capabilities/ Requirements	<ul style="list-style-type: none"> <li>▪ Logging capabilities exist across the entire communications architecture.</li> <li>▪ Logs are captured in command register.</li> <li>▪ Command register is capable of cross-checking and verifying log integrity.</li> </ul>
Expected Results	<ul style="list-style-type: none"> <li>▪ Command register verifies integrity of events throughout individual communication life cycles.</li> <li>▪ Command register notifies of integrity failure in events throughout individual communication life cycles.</li> </ul>
Actual Results	<ul style="list-style-type: none"> <li>▪ to be determined</li> </ul>
Overall Results	<ul style="list-style-type: none"> <li>▪ to be determined</li> </ul>

722 **5.2.3 Test Scenario 3: Log File Information Can Be Captured and Analyzed**

723 This test case will verify the capabilities of capturing and analyzing log data within the microgrid

724 network.

725 **Table 5-3 Test Procedure: Log File Information Can Be Captured and Analyzed**

Procedure	<ul style="list-style-type: none"> <li>Log file data is captured by the syslog aggregators on the NCCoE lab data collection network.</li> <li>Log files are routinely transferred by the syslog aggregators to Sumo Logic for analysis.</li> <li>Log file analysis results are presented to microgrid cyber analysts via a Sumo Logic dashboard.</li> </ul>
Architectural Requirements	<ul style="list-style-type: none"> <li>ability for log data to be captured and stored somewhere in the network</li> <li>ability to transfer log data to analytics engine</li> </ul>
Capabilities/ Requirements	<ul style="list-style-type: none"> <li>All microgrid applications and services can record data in an exportable and accessible log.</li> <li>ability to analyze log files based on predetermined audit logic</li> </ul>
Expected Results	<ul style="list-style-type: none"> <li>Log data is collected across the utility and microgrid networks.</li> <li>Log data is successfully transferred to analysis engine.</li> <li>Analysis engine can read and interpret all logs that are ingested.</li> </ul>
Actual Results	<ul style="list-style-type: none"> <li>to be determined</li> </ul>
Overall Results	<ul style="list-style-type: none"> <li>to be determined</li> </ul>

726 **5.2.4 Test Scenario 4: Log File Analysis Can Be Shared**

727 This test case will verify that the log analysis findings can be shared through proper channels.

728 **Table 5-4 Test Procedure: Log File Analysis Can Be Shared**

Procedure	<ul style="list-style-type: none"> <li>A subset of analysis and/or log file data can be shared among utility and microgrid operators' Sumo Logic user accounts.</li> </ul>
Architectural Requirements	<ul style="list-style-type: none"> <li>A workstation can connect to Sumo Logic for reviewing log analysis.</li> </ul>
Capabilities Requirements	<ul style="list-style-type: none"> <li>analytical capabilities to interpret results from log files</li> </ul>

Expected Results	<ul style="list-style-type: none"> <li>Log analysis is used to understand system health and detect suspicious behavior.</li> <li>Log events are communicated to an analyst.</li> </ul>
Actual Results	<ul style="list-style-type: none"> <li>to be determined</li> </ul>
Overall Result	<ul style="list-style-type: none"> <li>to be determined</li> </ul>

729 **5.2.5 Test Scenario 5: Malicious Activity Is Detected**

730 This test case will verify the system’s ability to detect anomalous or malicious behavior on the network.

731 **Table 5-5 Test Procedure: Malicious Activity Is Detected**

Procedure	<ul style="list-style-type: none"> <li>Suspicious activity on the utility network is identified and alert(s) is generated.</li> <li>Suspicious activity is captured in log files.</li> <li>Suspicious activity in the cyber demarcation point is identified, and an alert(s) is generated.</li> </ul>
Architectural Requirements	<ul style="list-style-type: none"> <li>Holistic monitoring is enabled across the system.</li> <li>Logging is completed and delivered to log collector through secure means.</li> <li>Log analysis is performed.</li> </ul>
Capabilities Requirements	<ul style="list-style-type: none"> <li>ability to monitor device and network activities</li> <li>ability to collect logs on devices and across the networks</li> <li>ability to deliver logs to analysis engine</li> <li>proper analysis of logs</li> <li>notification of events found within logs</li> </ul>
Expected Results	<ul style="list-style-type: none"> <li>Log analysis is successfully completed, and any potentially malicious events are detected and alerts are created for an analyst.</li> </ul>
Actual Results	<ul style="list-style-type: none"> <li>to be determined</li> </ul>

Overall Result	<ul style="list-style-type: none"> <li>▪ to be determined</li> </ul>
----------------	--

732

733 **5.2.6 Test Scenario 6: Privileged User Access Is Managed**

734 This test case will verify that privileged users are authenticated and authorized to access only those  
 735 devices to which they have been given proper privileges.

736 **Table 5-6 Test Procedure: Privileged User Access Is Managed**

Procedure	<ul style="list-style-type: none"> <li>▪ Access the applications and services on the microgrid management network through ConsoleWorks.</li> </ul>
Architectural Requirements	<ul style="list-style-type: none"> <li>▪ ConsoleWorks system is placed at network access points for privileged users.</li> <li>▪ ConsoleWorks system controls all privileged user interaction</li> </ul>
Capabilities Requirements	<ul style="list-style-type: none"> <li>▪ ability to identify approved users for ConsoleWorks</li> <li>▪ ConsoleWorks will control access based on authentication and authorization of privileged users.</li> <li>▪ ConsoleWorks will be able to route privileged user interaction successfully to proper devices.</li> </ul>
Expected Results	<ul style="list-style-type: none"> <li>▪ Privileged users will be able to access the devices they are authorized to access.</li> <li>▪ Users will not be able to access devices they are not authorized to access.</li> </ul>
Actual Results	<ul style="list-style-type: none"> <li>▪ to be determined</li> </ul>
Overall Results	<ul style="list-style-type: none"> <li>▪ to be determined</li> </ul>

737 **5.3 Scenarios and Findings**

738 Security evaluation of the reference architecture involves assessing how well the architecture addresses  
 739 the security characteristics that it is intended to support. The Cybersecurity Framework Subcategories  
 740 were used to provide structure to the security assessment. Using the Cybersecurity Framework  
 741 Subcategories as a basis for organizing the analysis allows systematic consideration of the reference  
 742 architecture’s support for the intended security characteristics.

743 In the project description, we described a sequence of events that could lead to a malicious entity being  
744 able to masquerade as either a utility operator or a DER operator. If that were to occur, the utility could  
745 not trust the information that it would receive from the DER operators. Likewise, the DER operators  
746 could not trust the utility's information exchange.

747 This section analyzes the example solution in terms of the Cybersecurity Framework's specific  
748 Subcategories supported, creating trust in information exchanges between the utility and the microgrid  
749 operation. The example solution has not been completed. Therefore, the security characteristic analysis  
750 in this preliminary draft is incomplete.

### 751 5.3.1 Identity Management, Authentication, and Access Control

#### 752 *5.3.1.1 PR.AC-1: Identities and Credentials Are Issued, Managed, Verified, Revoked, and* 753 *Audited for Authorized Devices, Users, and Processes*

754 This Cybersecurity Framework Subcategory is supported in the example solution by the Xage Security  
755 Fabric, Cisco ISE, and ConsoleWorks. The utility can establish identities and credentials by using the Xage  
756 Manager. These identities and credentials are used by the utility gateway in the cyber demarcation  
757 point. The utility gateway is implemented by the Xage Edge Node and Xage Enforcement Point. The  
758 microgrid operator can verify identities and credentials by using Cisco ISE. These permissions are used  
759 by the microgrid gateway in the cyber demarcation point and by the DER gateway on the microgrid.  
760 These gateways are implemented in the example solution by BlackRidge Technologies TAC Gateways.

761 ConsoleWorks manages the privileged access credentials used to access the management interfaces of  
762 Cisco ISE, the BlackRidge Enterprise Manager, and Cisco Cyber Vision.

#### 763 *5.3.1.2 PR.AC-3: Remote Access Is Managed*

764 This Cybersecurity Framework Subcategory is supported by the reference architecture's cyber  
765 demarcation point. The cyber demarcation point uses identity to control access by the utility to DER  
766 devices on the microgrid network. The reference architecture has two separate policy domains: the  
767 utility domain and the microgrid operator domain. The cyber demarcation point consists of a utility  
768 gateway and a microgrid gateway. The utility controls the identities used and the access policy enforced  
769 by the utility gateway. The microgrid operator controls the identities used and the access policy  
770 enforced by the microgrid gateway. These two gateways control remote access by the utility to DER  
771 devices on the microgrid network.

#### 772 *5.3.1.3 PR.AC-4: Access Permissions and Authorizations Are Managed, Incorporating the* 773 *Principles of Least Privilege and Separation of Duties*

774 This Cybersecurity Framework Subcategory is supported in the example solution by the Xage Security  
775 Fabric, Cisco ISE, Anterix, and TDi ConsoleWorks. The utility can establish access permissions using the

776 Xage Manager. The permissions are used by the utility gateway in the cyber demarcation point. The  
777 utility gateway is implemented by the Xage Gateway and Xage Enforcement Point. The microgrid  
778 operator can configure access permissions using Cisco ISE. These permissions are used by the microgrid  
779 gateway in the cyber demarcation point and by the DER gateway on the microgrid. These gateways are  
780 implemented in the example solution by BlackRidge Technologies TAC Gateways.

781 The Anterix LTE network at UMD uses LTE's access control features to determine what devices are  
782 allowed to access the wireless network.

783 ConsoleWorks manages privileged user access permissions that determine who has access to the  
784 management interfaces of Cisco ISE, Cisco Cyber Vision, and BlackRidge enterprise manager. The access  
785 permission also details what actions a user is allowed to perform on each of these systems.

#### 786 *5.3.1.4 PR.AC-5: Network Integrity Is Protected (e.g., Network Segregation, Network* 787 *Segmentation)*

788 This Cybersecurity Framework Subcategory is supported by the reference architecture's cyber  
789 demarcation point and by network segmentation within the microgrid.

790 The utility is not exchanging information directly with the microgrid, but it is exchanging information  
791 through the cyber demarcation point. The reference architecture provides gateways to represent the  
792 microgrid and utility independently. Thus, the utility would manage communications and security  
793 interactions through its gateway; the microgrid operator would also manage its gateway and the assets  
794 on its side.

795 The microgrid implemented in the example solution has several distinct networks as shown in Figure 5:  
796 Data Analysis and Visualization. These networks are separated by pfSense virtual firewalls that isolate  
797 each network and control traffic and access among the networks.

## 798 5.3.2 Data Security

### 799 *5.3.2.1 PR.DS-1: Data at Rest Is Protected*

800 This Cybersecurity Framework Subcategory is supported by the reference architecture's command  
801 register capability. The command register provides protection at rest for the audit trail of information  
802 exchanges between the utility and microgrid operator. The ledger ensures the integrity of the audit trail  
803 records. The distributed nature of the ledger ensures availability of the audit trail records. In the  
804 example solution, the command register is implemented using Spherical Analytics' Immutably services.  
805 As records are received, Immutably invokes notaries that sign the records and attest to attributes of the  
806 records such as time received and source. This realizes the objective of a distributed, immutable audit  
807 trail of information exchanges.

808 The Xage Security Fabric uses a distributed ledger to protect security information, such as credentials  
809 and access permissions, that are needed by the Xage Edge Nodes and Xage Enforcement Points. The  
810 distributed ledger protects the integrity and availability of this information.

#### 811 *5.3.2.2 PR.DS-2: Data in Transit Is Protected*

812 This Cybersecurity Framework Subcategory is supported using VPNs to encrypt traffic between the  
813 NCCoE lab and the solar arrays located on parking garages at UMD.

814 The example solution includes two physically separate sites—the NCCoE lab and the UMD  
815 infrastructure. Data in transit between the NCCoE and UMD is protected by a VPN by using two pfSense  
816 virtual firewalls that encrypt all traffic between the NCCoE lab and UMD.

817 The example solution also includes an LTE network that carries traffic from the termination point of the  
818 pfSense VPN in a UMD campus building to the solar arrays' control systems at two parking garages.  
819 Separate point-to-point VPNs over the LTE network connect each solar array to the pfSense VPN  
820 connection to the NCCoE lab. The point-to-point VPNs encrypt traffic from the UMD campus building to  
821 the solar array control systems at the parking garages. The LTE network itself also provides data  
822 encryption and data-integrity protection features.

823 A utility implementing its own private LTE network can choose to adopt additional security features to  
824 improve its security posture, as it deems most appropriate to its own mission and business  
825 considerations.

#### 826 *5.3.2.3 PR.DS-6: Integrity-Checking Mechanisms Are Used to Verify Software, Firmware, 827 and Information Integrity*

828 This Cybersecurity Framework Subcategory is supported by the reference architecture's command  
829 register.

830 The command register provides an immutable, fully distributed audit trail accessible by all parties  
831 involved in information exchanges. Using the command register, the full sequence of events between  
832 the utility and DER operators is observable by all parties.

833 In the example solution, the command register is implemented using a distributed ledger system. Each  
834 DER operator and the utility create a partial audit trail that is aggregated by the ledger to record all steps  
835 in an information exchange. The integrity of the ledger is verifiable, ensuring the integrity of the  
836 recorded audit trail.

### 837 5.3.3 Anomalies and Events

#### 838 *5.3.3.1 DE.AE-1: A Baseline of Network Operations and Expected Data Flows for Users* 839 *and Systems Is Established and Managed*

840 This Cybersecurity Framework Subcategory is supported by the utility cyber monitoring and microgrid  
841 cyber monitoring components of the cyber demarcation point in the reference architecture. The cyber  
842 monitoring components are self-training. They monitor network traffic and observe the normal behavior  
843 and flow of information into and out of the cyber demarcation.

844 In the example solution, the cyber monitoring components are implemented by Radiflow iSID and Cisco  
845 Cyber Vision. Each of these systems independently learns the expected traffic flows. If the flows are  
846 intentionally changed from those initially learned, the monitoring components can relearn the flows, or  
847 the expected flows can be manually configured to include changes.

#### 848 *5.3.3.2 DE.AE-2: Detected Events Are Analyzed to Understand Attack Targets and Methods*

849 This Cybersecurity Framework Subcategory is supported by the utility cyber monitoring and microgrid  
850 cyber monitoring components of the cyber demarcation point and data analysis and visualization in the  
851 reference architecture.

852 In the example solution, the cyber monitoring components are implemented by Radiflow iSID and Cisco  
853 Cyber Vision. Each of these products has multiple analytic and reporting capabilities that can identify  
854 known cyber-attack techniques and help cyber analysts understand new attack methods and targets.

855 Data analysis and visualization analyzes log data from services on the microgrid network to identify  
856 suspicious behavior and to alert analysts. Log data is compared with the expected normal behavioral  
857 characteristics that are learned over time. Deviations from the expected normal behavior are reported  
858 as events.

#### 859 *5.3.3.3 DE.AE-3: Event Data Are Collected and Correlated from Multiple Sources and* 860 *Sensors*

861 This Cybersecurity Framework Subcategory is supported by the reference architecture's data analysis  
862 and visualization capability. The data analysis and visualization capability collects log information from  
863 multiple sources within the microgrid network and sends this data to a cloud analytics platform. At the  
864 cloud analytics platform, the log data is analyzed to identify evidence of malicious or unexpected  
865 activity.

866 In the example solution, this capability is implemented using syslog-ng syslog aggregators and the Sumo  
867 Logic cloud analytics platform. Systems and applications within the microgrid send their syslog records  
868 to one of three syslog-ng aggregators. The aggregators forward the log data to the Sumo Logic cloud  
869 analytics platform for analysis.

870 While not incorporated in the example solution, the cloud analytics platform allows controlled sharing  
871 of information from the DER operators to the utility. The utility can also share analytic results with the  
872 DER operators.

873 This Cybersecurity Framework Subcategory is supported by the utility monitoring and microgrid  
874 monitoring components of the cyber demarcation point. These components can collect monitoring data  
875 from multiple locations within the cyber demarcation point for correlation. In the example solution, this  
876 does not happen because Cisco Cyber Vision and Radiflow iSID, which implement the microgrid and  
877 utility cyber monitoring, are each configured to use a single sensor.

878 This Cybersecurity Framework Subcategory is supported by the command register in the reference  
879 architecture. The command register captures a complete audit trail of information exchanges between a  
880 utility and DER operators who provide power to the utility. This audit trail can be analyzed for anomalies  
881 in the way information exchanges occur. In the example solution, Spherical Analytics Immutably  
882 supports such analysis and reporting.

#### 883 *5.3.3.4 DE.AE-5: Incident Alert Thresholds Are Established*

884 This Cybersecurity Framework Subcategory is supported by the utility cyber monitoring and microgrid  
885 cyber monitoring components of the cyber demarcation point as well as by the log analysis capability.  
886 Each of these monitoring and analysis capabilities has established thresholds for detecting anomalies  
887 and generating alerts.

### 888 **5.3.4 Security Continuous Monitoring**

#### 889 *5.3.4.1 The Information System and Assets Are Monitored to Identify Cybersecurity Events* 890 *and Verify the Effectiveness of Protective Measures*

891 This Cybersecurity Framework Subcategory is supported by the utility cyber monitoring and microgrid  
892 cyber monitoring components of the cyber demarcation point, and by the log analysis capability. Each of  
893 these monitors aspects of the system and identifies cybersecurity events.

#### 894 *5.3.4.2 DE.CM-2: The Physical Environment Is Monitored to Detect Potential Cybersecurity* 895 *Events*

896 This Cybersecurity Framework Subcategory is supported by the physical security systems at the NCCoE  
897 and UMD. Both the NCCoE and UMD have physical access control systems in place to control and  
898 monitor access to the physical locations where the example solution components are installed. NIST  
899 monitors the NCCoE physical access control system. UMD monitors its physical security system.

#### 900 *5.3.4.3 DE.CM-4: Malicious Code Is Detected*

901 This Cybersecurity Framework Subcategory is supported by the utility cyber monitoring and microgrid  
902 cyber monitoring components of the cyber demarcation point. These components can detect some  
903 malicious code types based on analysis of monitored network traffic. In the example solution, these  
904 components are implemented by Radiflow iSID and Cisco Cyber Vision, each of which has some  
905 malicious-code-detection capability.

#### 906 *5.3.4.4 DE.CM-7: Monitoring for Unauthorized Personnel, Connections, Devices, and* 907 *Software Is Performed*

908 This Cybersecurity Framework Subcategory is supported by the microgrid cyber monitoring component  
909 of the cyber demarcation point in the reference architecture. Additionally, it is supported by Cisco ISE in  
910 the example solution.

911 The microgrid cyber monitoring component, implemented in the example solution by Cisco Cyber Vision,  
912 develops a model of the expected devices and information flows. Unexpected devices or connections  
913 are detected and reported. Additionally, Cisco ISE is used to manage identities and network access to  
914 the microgrid network. Unauthorized attempts to connect to or use the microgrid network are detected  
915 and reported.

## 916 **6 Future Project Considerations**

917 The NCCoE recognizes that the example solution described in this practice guide demonstrates some of  
918 the tenets and principles of a zero trust architecture as defined in [NIST SP 800-207, Zero Trust](#)  
919 [Architecture](#). While most discussions around zero trust architectures focus on implementations for IT  
920 business networks and use cases, future NCCoE Energy Sector projects might consider implementing a  
921 zero trust architecture in an ICS environment. For example, we might consider extending this example  
922 solution to include dynamic access control for DERs or other grid-edge devices connecting to the  
923 distribution grid.

924 **Appendix A List of Acronyms**

<b>CISA</b>	Cybersecurity and Infrastructure Security Agency
<b>DER</b>	Distributed Energy Resource
<b>EPRI</b>	Electric Power Research Institute
<b>EPS</b>	Electric Power System
<b>ICS</b>	Industrial Control System
<b>ICS-CERT</b>	Industrial Control Systems–Computer Emergency Readiness Team
<b>IIoT</b>	Industrial Internet of Things
<b>IT</b>	Information Technology
<b>LTE</b>	Long-Term Evolution
<b>NCCoE</b>	National Cybersecurity Center of Excellence
<b>NIST</b>	National Institute of Standards and Technology
<b>OT</b>	Operational Technology
<b>UMD</b>	University of Maryland
<b>VPN</b>	Virtual Private Network
