

Filtering live hosts and domains

We'll explore techniques for filtering live hosts and domains from the vast amount of subdomains we have gathered till now during our reconnaissance process.

We will use two tools to accomplish this task - one is **HTTPProbe** and other one is **Eyewitness**.

First we will use HTTPProbe.

HTTPProbe is an awesome tool that takes a list of domains and probe for working http and https servers.

So, we already have the list of subdomains we have gathered till now. We just have to pass it to HTTPProbe

- Finding Live hosts with HTTPProbe

```
cat test.txt | httpprobe -c 50
```

Once we have the live hosts, we will use another tool to get the screenshot of them. In the real world, it will be really time consuming to check which hosts has a application running which does not. We can use this tool to make our life easier.

- Screenshot live hosts with Eyewitness

```
python3 EyeWitness.py -f file.txt
```
