

# Cryptography

## Module 18

Unmask the **Invisible Hacker**.

# Market Survey 2014: The Year of Encryption

**60%** of those survey said that Edward Snowden revelations have made them more aware of data security

Among the 60%, approximately **70%** have been directly influenced to look at new data security systems

**94%** of people looking to invest in new systems are specifically examining secure (encryption) electronic data security systems

Only **17%** of those surveyed said their existing secure information sharing system was easy to use

**100%** of those not interested in security systems admitted to regularly sharing sensitive/ confidential data with external third parties

Over **2/3** of people felt that government certification combined with ease of use would be deciding factors when selecting a data security solution

**One in two** people now perceive the Cloud to be less secure as result of Snowden

**One third** of those surveyed were not that upcoming EU DPA reforms would impact the way they or their organization handles and protects data

## Case Study: Heartbleed

Heartbleed is a security flaw in the **OpenSSL** cryptographic software library, which allows data traversal over **SSL/TLS in plain-text**

Heartbleed exploits a built-in feature of OpenSSL called **heartbeat**

Attackers exploit this vulnerability to get information such as OpenSSL **private** keys, OpenSSL **secondary** keys, up to **64kb of memory** from the affected server, **usernames** and **passwords**, etc.

Versions of OpenSSL affected by Heartbleed include **1.0.1 to 1.0.1f**

Updating OpenSSL to version 1.0.1g or higher resolves the vulnerability

# Case Study: Poodlebleed

- 
- Poodlebleed (**Padding Oracle On Downgraded Legacy Encryption**) is a security vulnerability in the design of SSL 3.0
  - Attacker exploits this vulnerability to **decrypt ciphertext in transit** between a server and a browser, by means of padding oracle side-channel attack
  - **Countermeasures:**
    - Completely **disable SSL 3.0** on the client side and the server side
    - Implement **anti-POODLE record splitting**

# Cryptography

01

Cryptography is the **conversion of data** into a scrambled code that is decrypted and sent across a private or public network

02

Cryptography is used to protect confidential data such as **email messages**, chat sessions, **web transactions**, personal data, **corporate data**, e-commerce applications, etc.

03

## Objectives

- Confidentiality
- Integrity

- Authentication
- Non-repudiation

04

# Types of Cryptography

## Symmetric Encryption

Symmetric encryption (secret-key, shared-key, and private-key) **uses the same key** for encryption as it does for decryption

## Asymmetric Encryption

Asymmetric encryption (public-key) **uses different encryption keys** for encryption and decryption. These keys are known as public and private keys

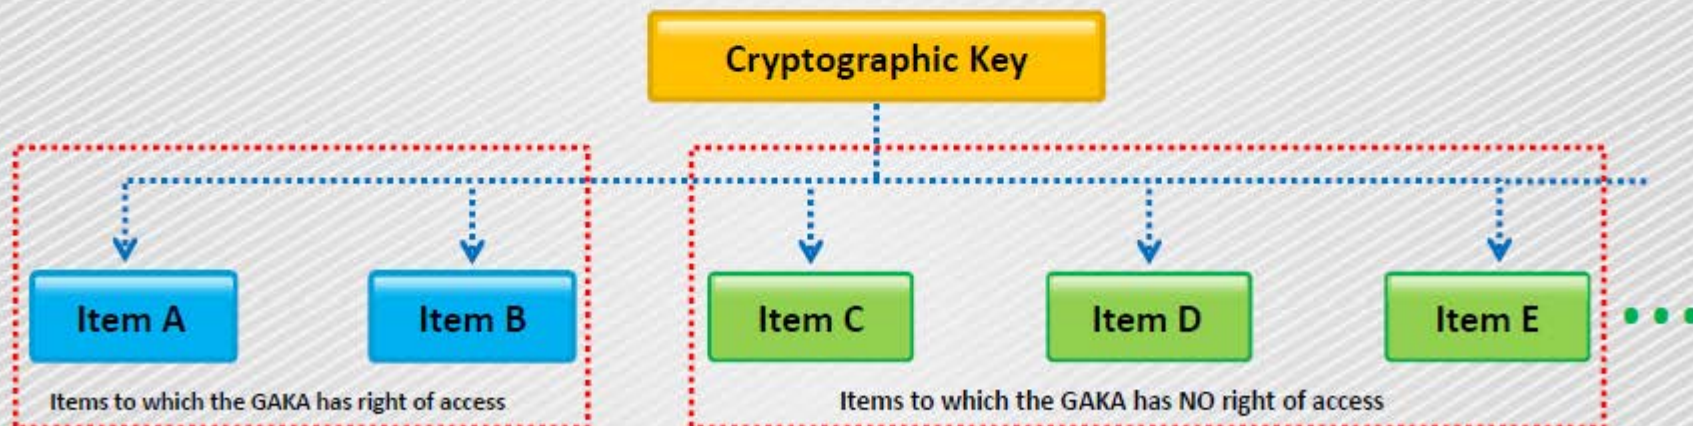

# Government Access to Keys (GAK)

Government Access to Keys means that software companies will give **copies of all keys**, (or at least enough of the key that the remainder could be cracked) to the government

The government promises that they will hold on to the keys in a **secure way**, and will only use them when a **court issues a warrant** to do so

To the government, this issue is similar to the **ability to wiretap phones**

# Ciphers

Ciphers are **algorithms** used to encrypt or decrypt the data

## Modern Ciphers

### Classical Ciphers

#### Substitution cipher

A block of plaintext is replaced with ciphertext

#### Transposition cipher

The letters of the plaintext are shifted about to form the cryptogram

### Based on the type of key used

#### Private Key

Same key is used for encryption and decryption

#### Public Key

Two different keys are used for encryption and decryption

### Based on the type of input data

#### Block Cipher

Encrypts block of data of fixed size

#### Stream Cipher

Encrypts continuous streams of data

# Data Encryption Standard (DES)

The algorithm is designed to **encipher** and **decipher** blocks of data consisting of **64 bits** under control of a 56-bit key

DES is the **archetypal block cipher** — an algorithm that takes a fixed-length string of plaintext bits and transforms it into a ciphertext bitstring of the same length

Due to the **inherent weakness** of DES with today's technologies, some organizations repeat the process three times (3DES) for added strength, until they can afford to update their equipment to AES capabilities

# Advanced Encryption Standard (AES)

## AES Pseudocode

AES is a **symmetric-key** algorithm for securing sensitive but unclassified material by U.S. government agencies

AES is an **iterated block cipher**, which works by repeating the same operation **multiple** times

It has a **128-bit** block size, with key sizes of 128, 192, and 256 bits, respectively for AES-128, AES-192, and AES-256

```
Cipher (byte in[4*Nb], byte out[4*Nb],  
word w[Nb*(Nr+1)])  
begin  
    byte state[4,Nb]  
    state = in  
    AddRoundKey(state, w)  
    for round = 1 step 1 to Nr-1  
        SubBytes(state)  
        ShiftRows(state)  
        MixColumns(state)  
        AddRoundKey(state, w+round*Nb)  
    end for  
    SubBytes(state)  
    ShiftRows(state)  
    AddRoundKey(state, w+Nr*Nb)  
    out = state  
end
```

# RC4, RC5, RC6 Algorithms

## RC4

A variable **key size stream cipher** with byte-oriented operations, and is based on the use of a random permutation

## RC5

It is a **parameterized algorithm** with a variable block size, a variable key size, and a variable number of rounds. The key size is **128-bits**

## RC6

RC6 is a **symmetric key block cipher** derived from RC5 with two additional features:

- Uses **Integer multiplication**
- Uses **four 4-bit working registers** (RC5 uses two 2-bit registers)

## RC5 Algorithm

# The DSA and Related Signature Schemes

## Digital Signature Algorithm

FIPS 186-2 specifies the Digital Signature Algorithm (DSA) that may be used in the **generation and verification of digital signatures** for sensitive, unclassified applications

## Digital Signature

The digital signature is **computed using a set of rules** (i.e., the DSA) **and a set of parameters** such that the identity of the signatory and integrity of the data can be verified

## Each entity creates a public key and corresponding private key

1. Select a prime number  $q$  such that  $2^{159} < q < 2^{160}$
2. Choose  $t$  so that  $0 \leq t \leq 8$
3. Select a prime number  $p$  such that  $2^{511+64t} < p < 2^{512+64t}$  with the additional property that  $q$  divides  $(p-1)$
4. Select a generator  $\alpha$  of the unique cyclic group of order  $q$  in  $\mathbb{Z}_p^*$
5. To compute  $\alpha$ , select an element  $g$  in  $\mathbb{Z}_p^*$  and compute  $g^{(p-1)/q} \bmod p$
6. If  $\alpha = 1$ , perform step five again with a different  $g$
7. Select a random  $a$  such that  $1 \leq a \leq q-1$
8. Compute  $y = \alpha^a \bmod p$

The public key is  $(p, q, \alpha, y)$ . The private key is  $a$ .

# RSA (Rivest Shamir Adleman)

RSA is an **Internet encryption and authentication system** that uses an algorithm developed by Ron Rivest, Adi Shamir, and Leonard Adleman

01

RSA encryption is widely used and is one of the **de-facto encryption standard**

02

It uses **modular arithmetic** and **elementary number theories** to perform computations using two large prime numbers

03

# The RSA Signature Scheme

## Algorithm Key generation for the RSA signature scheme

SUMMARY: each entity creates an RSA public key and a corresponding private key. Each entity  $A$  should do the following:

1. Generate two large distinct random primes  $p$  and  $q$ , each roughly the same size.
2. Compute  $n = pq$  and  $\phi = (p - 1)(q - 1)$ .
3. Select a random integer  $e$ ,  $1 < e < \phi$ , such that  $\gcd(e, \phi) = 1$ .
4. Use the extended Euclidean algorithm (Algorithm 2.107) to compute the unique integer  $d$ ,  $1 < d < \phi$ , such that  $ed \equiv 1 \pmod{\phi}$ .
5.  $A$ 's public key is  $(n, e)$ ;  $A$ 's private key is  $d$ .

## Algorithm RSA signature generation and verification

SUMMARY: entity  $A$  signs a message  $m \in \mathcal{M}$ . Any entity  $B$  can verify  $A$ 's signature and recover the message  $m$  from the signature.

1. *Signature generation.* Entity  $A$  should do the following:
  - (a) Compute  $\tilde{m} = R(m)$ , an integer in the range  $[0, n - 1]$ .
  - (b) Compute  $s = \tilde{m}^d \pmod{n}$ .
  - (c)  $A$ 's signature for  $m$  is  $s$ .
2. *Verification.* To verify  $A$ 's signature  $s$  and recover the message  $m$ ,  $B$  should:
  - (a) Obtain  $A$ 's authentic public key  $(n, e)$ .
  - (b) Compute  $\tilde{m} = s^e \pmod{n}$ .
  - (c) Verify that  $\tilde{m} \in \mathcal{M}_R$ ; if not, reject the signature.
  - (d) Recover  $m = R^{-1}(\tilde{m})$ .

# Example of RSA Algorithm

$P = 61$       $\leq$  first prime number (destroy this after computing E and D)  
 $Q = 53$       $\leq$  second prime number (destroy this after computing E and D)  
 $PQ = 3233$       $\leq$  modulus (give this to others)  
 $E = 17$       $\leq$  public exponent (give this to others)  
 $D = 2753$       $\leq$  private exponent (keep this secret!)

Your **public key** is (E,PQ).

Your **private key** is D.

The encryption function is:  $\text{encrypt}(T) = (T^E) \bmod PQ$   
 $= (T^{17}) \bmod 3233$

The decryption function is:  $\text{decrypt}(C) = (C^D) \bmod PQ$   
 $= (C^{2753}) \bmod 3233$

To encrypt the plaintext value 123, do this:

$\text{encrypt}(123) = (123^{17}) \bmod 3233$   
 $= 337587917446653715596592958817679803 \bmod 3233$   
 $= 855$

To decrypt the cipher text value 855, do this:

$\text{decrypt}(855) = (855^{2753}) \bmod 3233$   
 $= 123$

# Message Digest (One-way Hash) Functions

Document

Message Digest Function

`a14092af948b938569584e5b8d8d307a`

Hash Value

Hash functions **calculate a unique fixed-size bit string** representation called a message digest of any arbitrary block of information

If any given bit of the function's input is changed, every output bit has a **50 percent** chance of changing

It is computationally infeasible to have two files with the **same message digest value**

**Note:** Message digests are also called one-way hash functions because they cannot be reversed

# Message Digest Function: MD5

MD5 Algorithm

MD5 algorithm takes a message of arbitrary length as input and outputs a 128-bit fingerprint or message digest of the input

MD5 is not collision resistant, use of latest algorithms such as SHA-2 and SHA-3 is recommended

MD5 hash is a 32-digit hexadecimal number

It is still deployed for digital signature applications, file integrity checking and storing passwords

Quick Checksum Verifier

# Secure Hashing Algorithm (SHA)

It is an algorithm for generating cryptographically secure one-way hash, published by the **National Institute of Standards and Technology** as a **U.S. Federal Information Processing Standard**

## SHA1

It produces a **160-bit digest** from a message with a maximum length of **(264 – 1) bits**, and resembles the MD5 algorithm

## SHA2

It is a family of two similar hash functions, with different block sizes, namely **SHA-256** that uses **32-bit words** and **SHA-512** that uses **64-bit words**

## SHA3

SHA-3 uses the **sponge construction** in which message blocks are **XORed** into the initial bits of the state, which is then invertibly permuted

# What is **SSH** (Secure Shell)?

- 1 SSH is a secure replacement for **telnet** and the **Berkeley remote-utilities** (rlogin, rsh, rcp, and rdist)
- 2 It provides an **encrypted channel** for remote logging, command execution and file transfers
- 3 Provides strong **host-to-host and user authentication**, and secure communication over an insecure Internet

**Note:** SSH2 is a more secure, efficient, and portable version of SSH that includes SFTP, an SSH2 tunneled FTP

# Public Key Infrastructure (PKI)

Public Key Infrastructure (PKI) is a **set of hardware, software, people, policies, and procedures** required to create, manage, distribute, use, store, and revoke **digital certificates**

## Components of PKI

**1**

### Certificate Management System

Generates, distributes, stores, and verifies certificates

**2**

### Digital Certificates

Establishes credentials of a person when doing online transactions

**3**

### Validation Authority (VA)

Stores certificates (with their public keys)

**4**

### Certificate Authority (CA)

Issues and verifies digital certificates

**5**

### End User

Requests, manages, and uses certificates

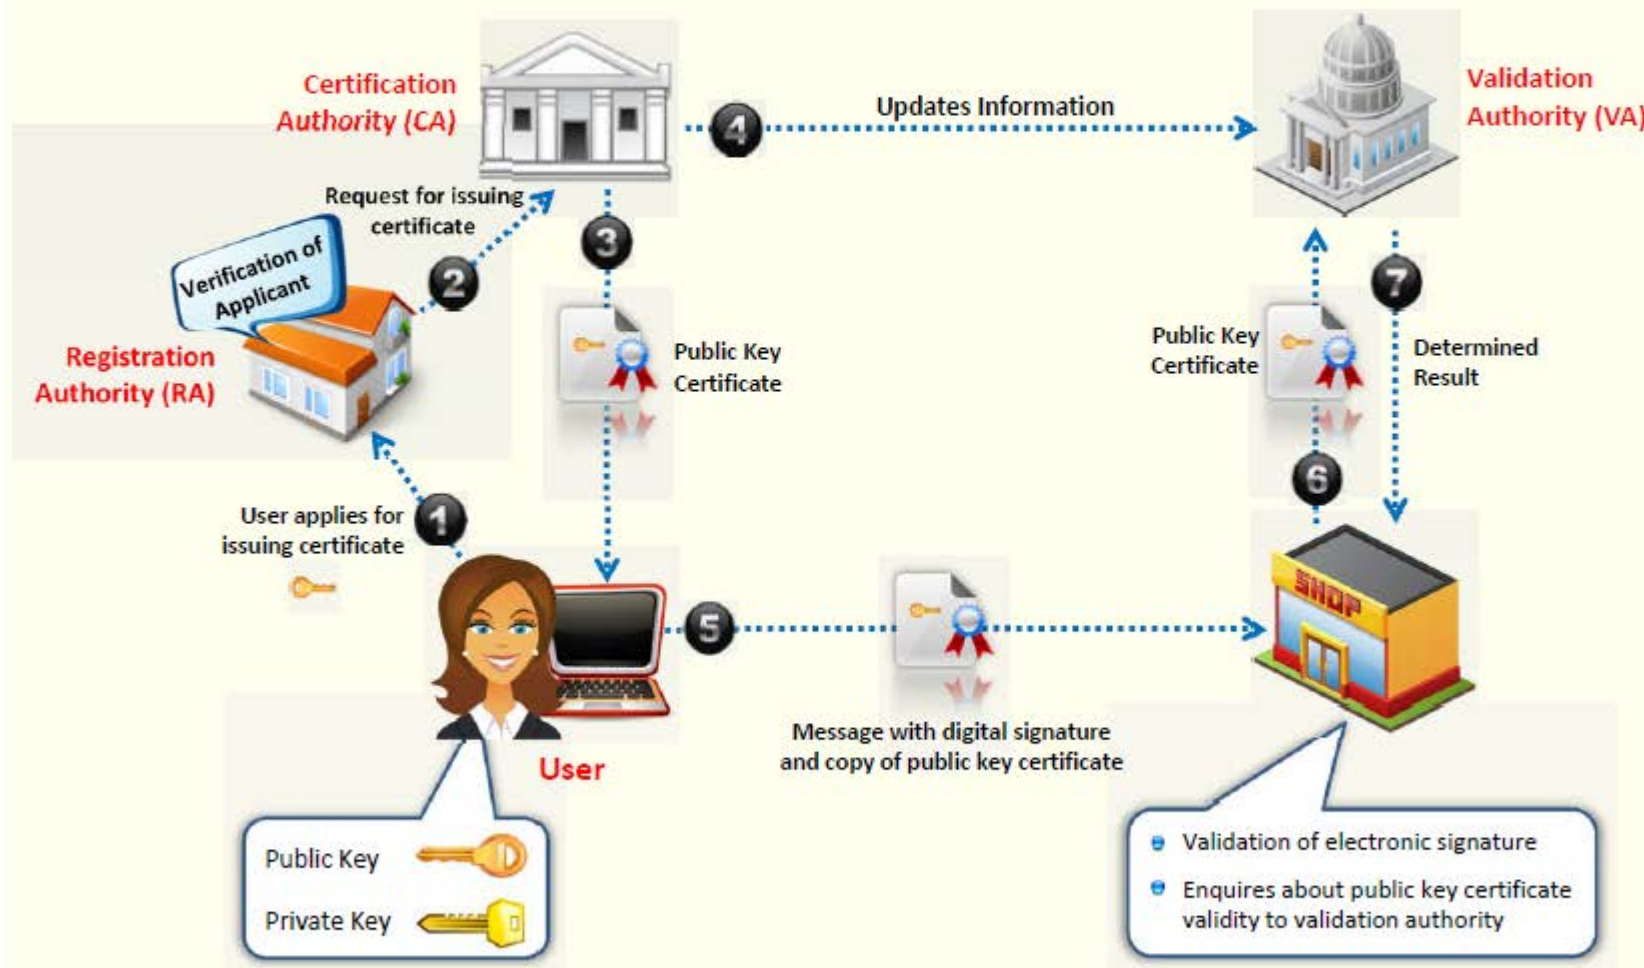

**6**

### Registration Authority (RA)

Acts as the verifier for the certificate authority

# Public Key Infrastructure (PKI)

# Signed Certificate (CA) Vs. Self Signed Certificate

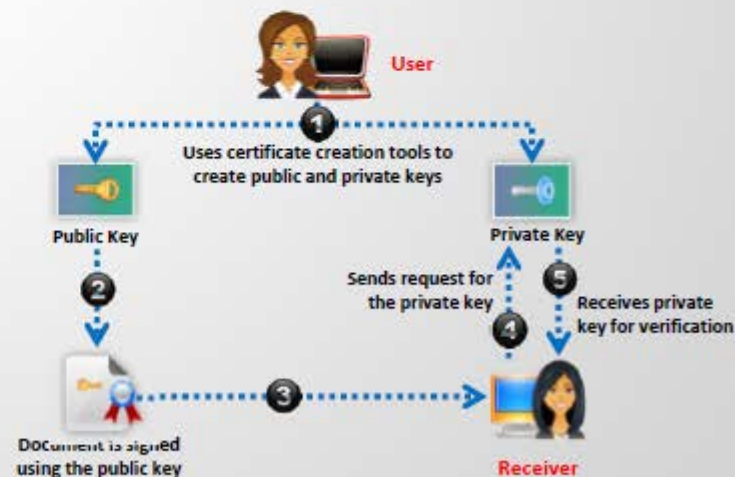

## Signed Certificate

- User approaches a trustworthy **Certification Authority (CA)** and purchases digital certificate
- User gets the **public key** from the CA, he signs the document using it
- The signed document is delivered to the receiver
- The receiver can verify the certificate by enquiring in **Validation Authority (VA)**
- VA verifies the certificate to the receiver but it does not **share private key**

## Self-signed Certificate

- User creates public and private keys using a tool such as **Adobe Reader, Java's keytool, Apple's Keychain**, etc.
- User uses public key to **sign the document**
- The **self-signed document** is delivered to the receiver
- The receiver request the user for his **private key**
- User **shares the private key** with the receiver

# Digital Signature

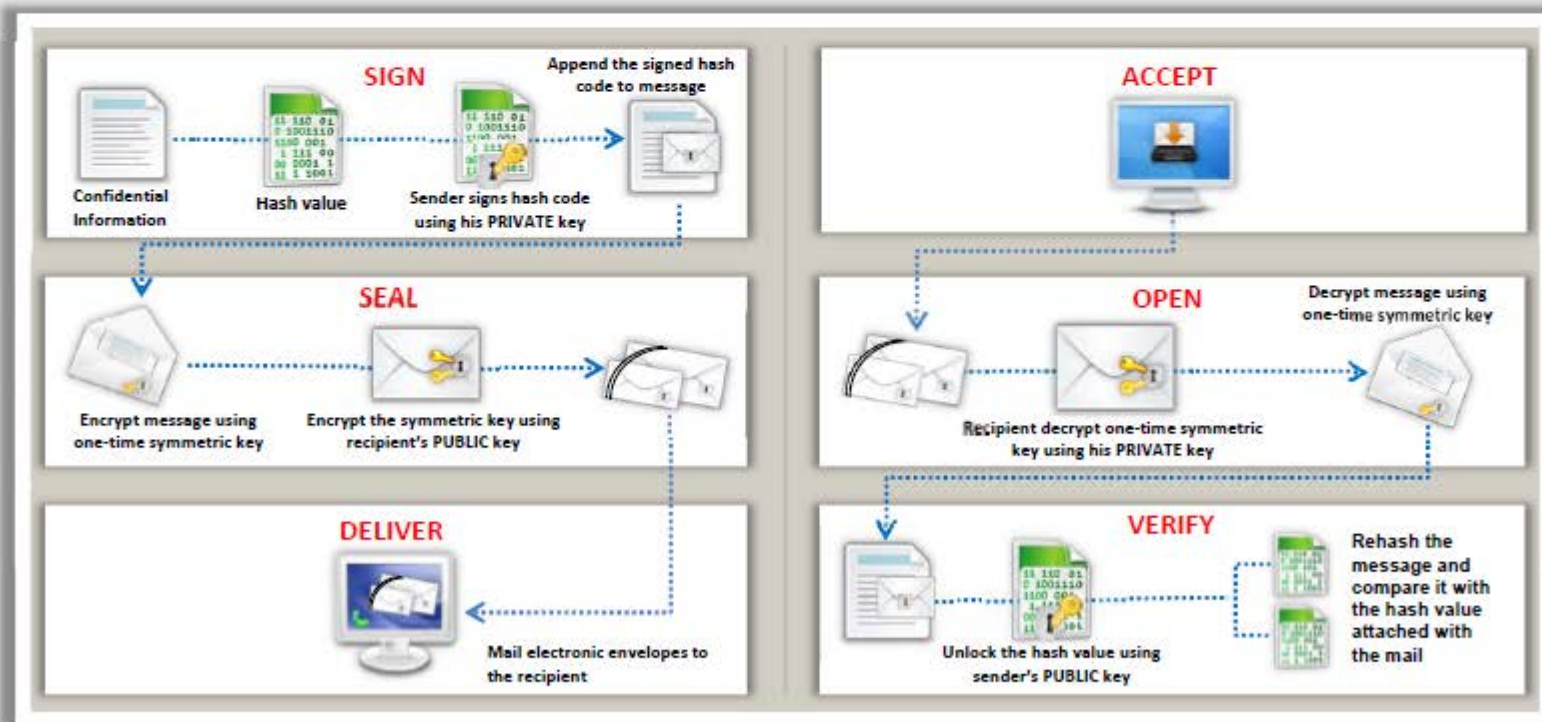

1

Digital signature used asymmetric cryptography to simulate the security properties of a **signature in digital, rather than written form**

2

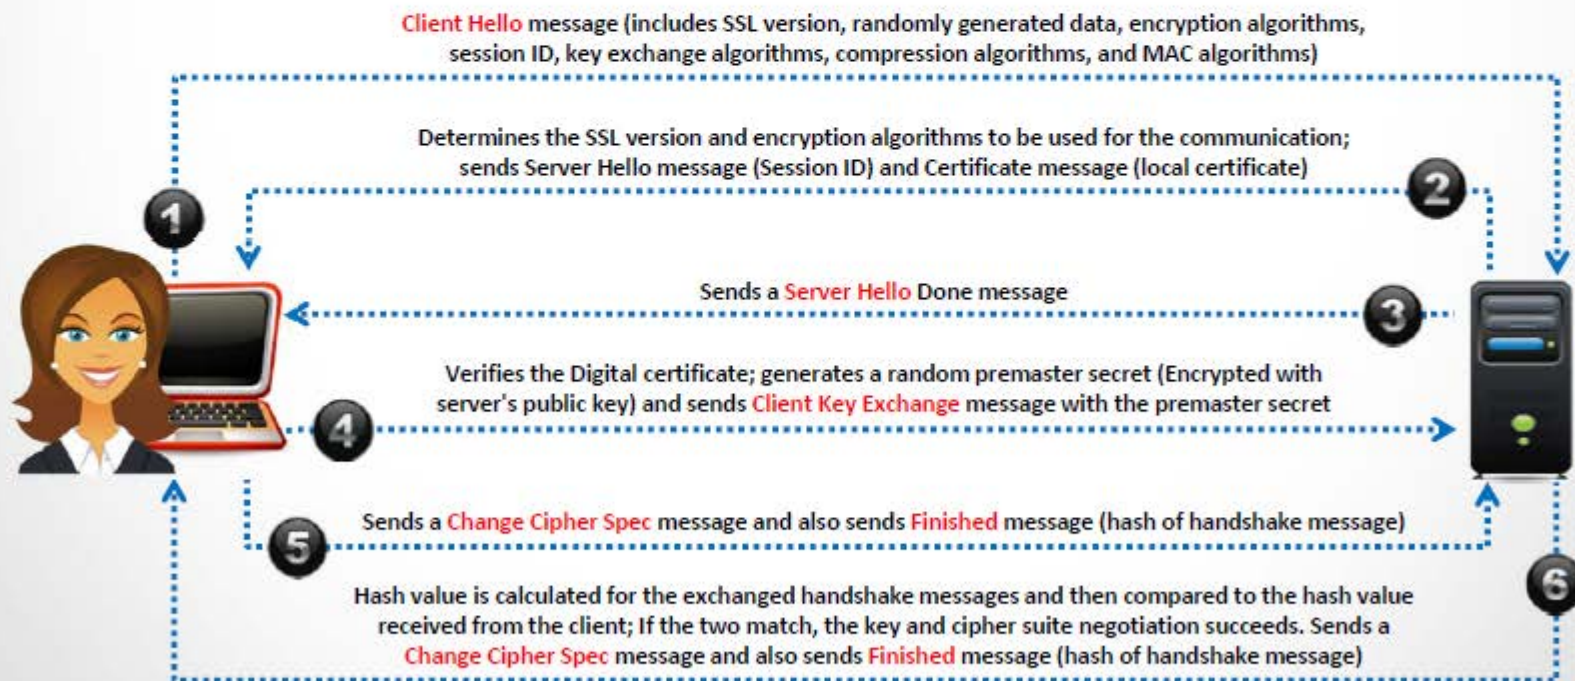

A digital signature may be further protected, by **encrypting the signed email** for confidentiality

# SSL (Secure Sockets Layer)

- SSL is an application layer protocol developed by Netscape for **managing the security** of a message transmission on the Internet
- It uses **RSA asymmetric (public key) encryption** to encrypt data transferred over SSL connections

# Transport Layer Security (TLS)

- TLS is a protocol **to establish a secure connection** between a client and a server and ensure privacy and integrity of information during transmission
- It uses the RSA algorithm with 1024 and 2048 bit strengths

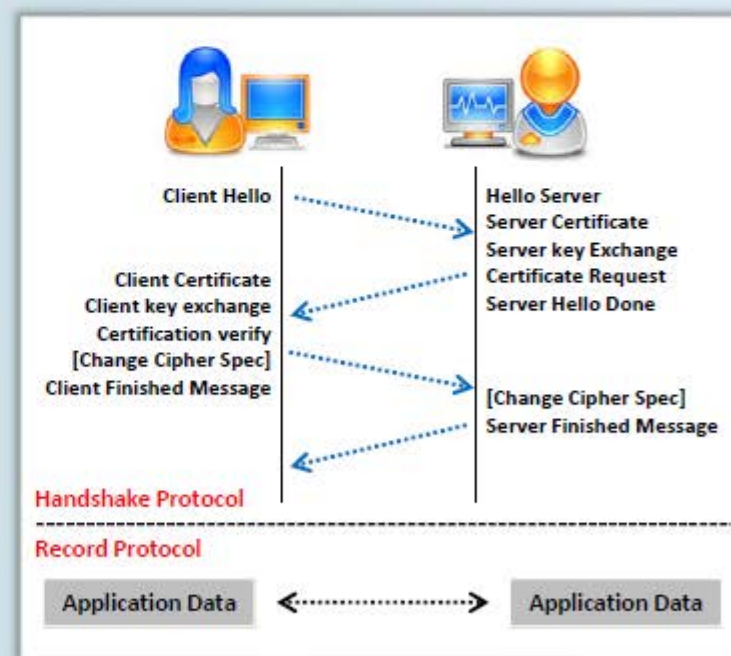

## TLS Handshake Protocol

It allows the client and server to authenticate each other, select encryption algorithm, and exchange symmetric key prior to data exchange

## TLS Record Protocol

It provides secured connections with an encryption method such as Data Encryption Standard (DES)

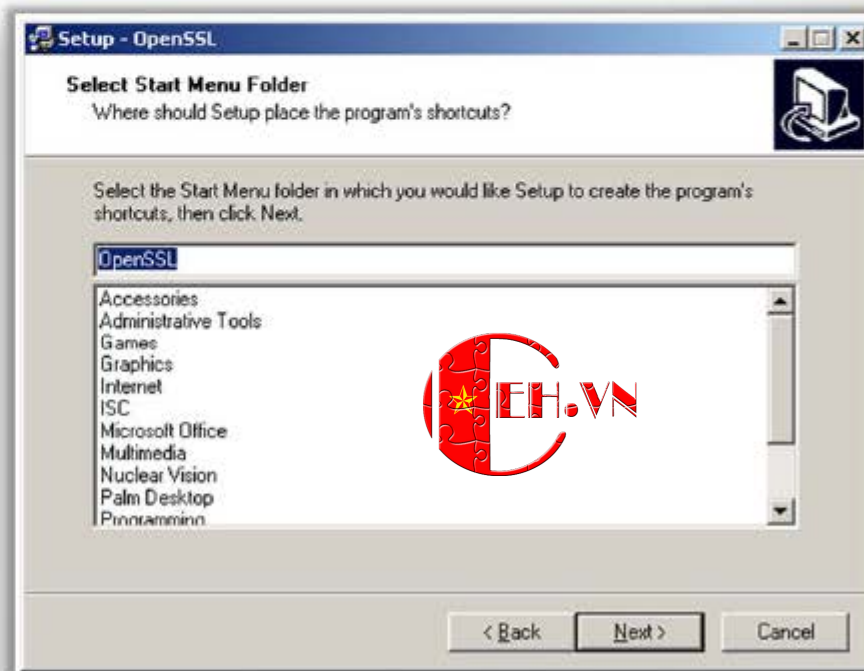

# Cryptography Toolkit: OpenSSL

- OpenSSL is an open source cryptography toolkit implementing the **Secure Sockets Layer (SSL v2/v3)** and **Transport Layer Security (TLS v1)** network protocols and related cryptography standards required by them
- The openssl program is a command line tool for using the various **cryptography functions** of OpenSSL's crypto library from the shell

## OpenSSL can be used for:

- Creation and management of private keys, public keys and parameters
- Public key cryptographic operations
- Creation of X.509 certificates, CSRs and CRLs
- Calculation of Message Digests
- Encryption and Decryption with Ciphers
- SSL/TLS Client and Server Tests
- Handling of S/MIME signed or encrypted mail
- Time Stamp requests, generation and verification

<https://www.openssl.org>

# Cryptography Toolkit: **Keyczar**

- Keyczar is an open source cryptographic toolkit designed to make it easier and safer for developers to use **cryptography in their applications**
- It **supports authentication** and **encryption** with both symmetric and asymmetric keys

<http://www.keyczar.org>

## Features

- Key rotation and versioning
- Safe default algorithms, modes, and key lengths
- Automated generation of initialization vectors and ciphertext signatures
- Java, Python, and C++ implementations
- International support in Java

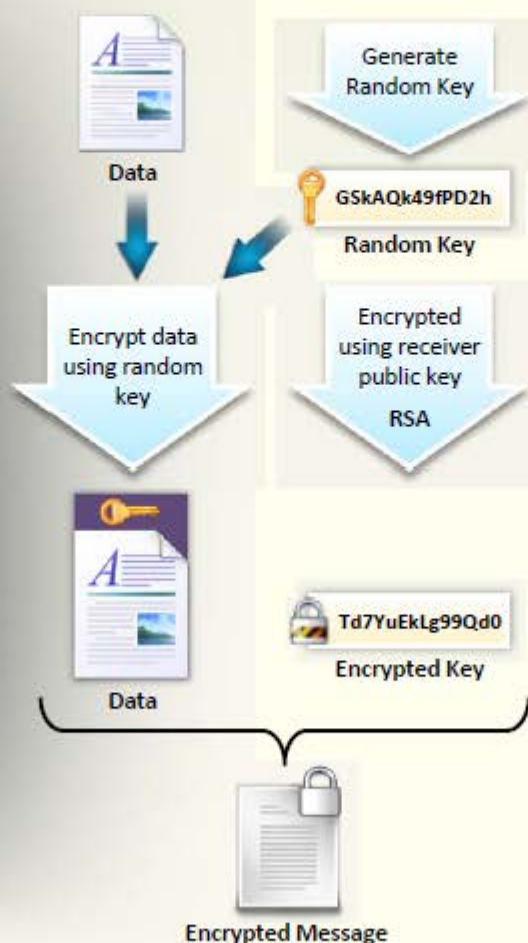

# Pretty Good Privacy (PGP)

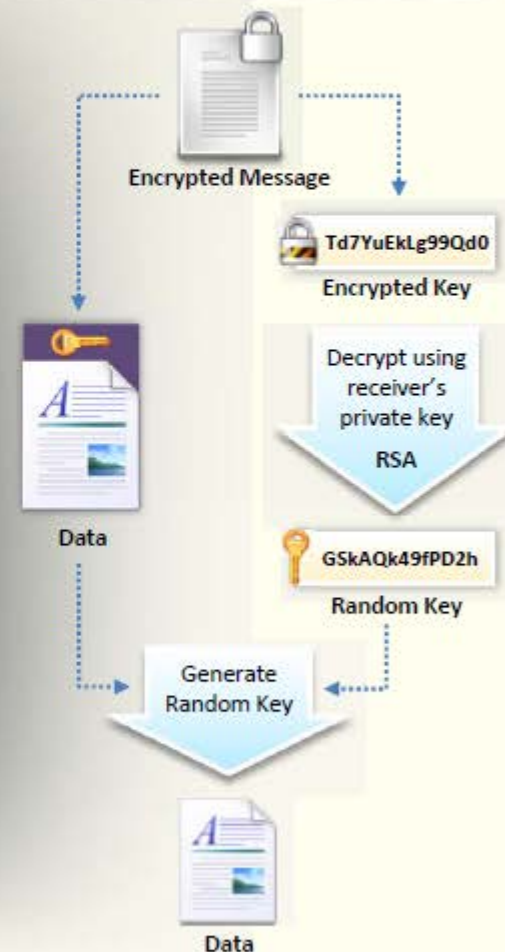

## Pretty Good Privacy

- PGP (Pretty Good Privacy) is a protocol used to **encrypt** and **decrypt** data that provides **authentication** and **cryptographic privacy**
- PGP is often used for data **compression**, **digital signing**, encryption and decryption of **messages**, **emails**, **files**, **directories**, and to enhance privacy of email communications
- PGP combines the best features of both **conventional** and **public key cryptography** and is therefore known as **hybrid cryptosystem**

## PGP Encryption

## PGP Decryption

# Disk Encryption

01

## Confidentiality

Disk encryption protects **confidentiality of the data** stored on disk by converting it into an unreadable code using disk encryption software or hardware

Privacy

Passphrase

Hidden Volumes

02

## Encryption

Disk encryption works in a similar way as **text message encryption** and protects data even when the OS not active

Volume Encryption

03

## Protection

With the use of an encryption program for your disk, you can **safeguard any information** to burn onto the disk, and keep it from falling into the wrong hands

Blue Ray

DVD

Backup

# Disk Encryption Tools: Symantec Drive Encryption and GiliSoft Full Disk Encryption

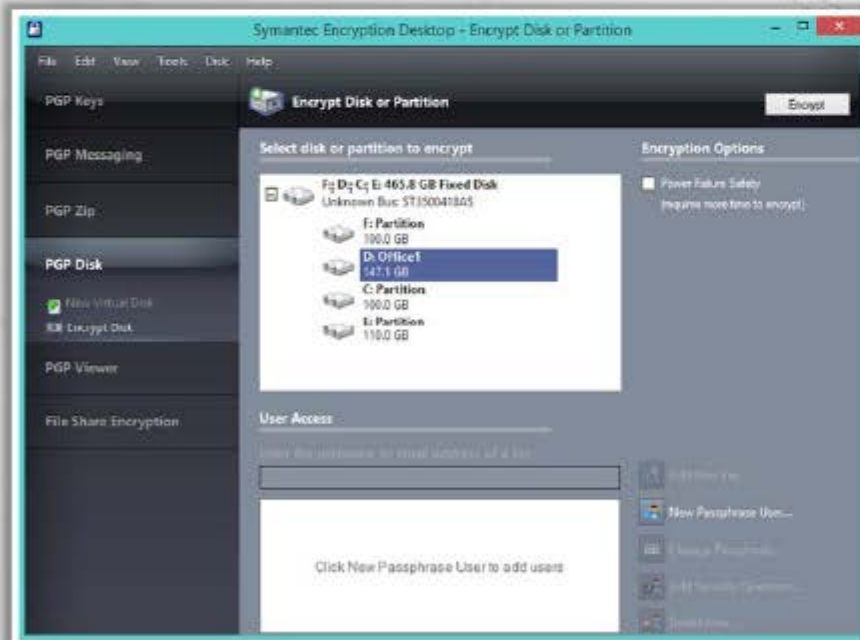

## Symantec Drive Encryption

- Symantec Drive Encryption provides **full disk encryption** for all data (user files, swap files, system files, hidden files, etc.) on desktops, laptops, and removable media
- It protects data from **unauthorized access**

## GiliSoft Full Disk Encryption

- GiliSoft Full Disk Encryption's offers encryption of all **disk partitions**, including the system partition
- It **provides automatic security** for all information on endpoint hard drives, including user data, operating system files and temporary and erased files

# Cryptography Attacks

- Cryptography attacks are based on the assumption that the cryptanalyst has access to the **encrypted information**

Ciphertext-only attack

Chosen-key attack

Known-plaintext attack

Adaptive chosen-plaintext attack

Chosen-plaintext

Timing attack

Chosen - ciphertext attack

Rubber hose attack

# Cryptography Attacks

## (Cont'd)

### Ciphertext-only Attack

Attacker has access to the cipher text; goal of this attack to **recover encryption key** from the ciphertext

### Adaptive Chosen-plaintext Attack

Attacker makes a **series of interactive queries**, choosing subsequent plaintexts based on the information from the previous encryptions

### Chosen-plaintext Attack

Attacker **defines his own plaintext**, feeds it into the cipher, and analyzes the resulting ciphertext

### Known-plaintext Attack

Attacker has **knowledge of some part of the plain text**; using this information the key used to generate ciphertext is deduced so as to decipher other messages

# Cryptography Attacks

## (Cont'd)

### Chosen-ciphertext Attack

Attacker obtains the plaintexts corresponding to an **arbitrary set** of ciphertexts of his own choosing

Extraction of cryptographic secrets (e.g. the password to an encrypted file) from a person by **coercion or torture**

### Rubber Hose Attack

### Chosen-key Attack

A **generalization** of the chosen-text attack

It is based on repeatedly measuring the **exact execution times** of modular exponentiation operations

### Timing Attack

# Code Breaking Methodologies

## Trickery and Deceit

It involves the use of **social engineering techniques** to extract cryptography keys

## Brute-Force

Cryptography keys are discovered by **trying every possible combination**

## One-Time Pad

A one-time pad contains many **non-repeating groups of letters** or number keys, which are chosen randomly

## Frequency Analysis

- It is the study of the frequency of letters or groups of letters in a **ciphertext**
- It works on the fact that, in any given stretch of written language, certain letters and **combinations of letters** occur with varying frequencies

# Brute-Force Attack

## Attack Scheme

Defeating a cryptographic scheme by **trying a large number of possible keys** until the correct encryption key is discovered

## Brute-Force Attack

Brute-force attack is a **high resource and time intensive process**, however, more certain to achieve results

## Success Factors

Success of brute force attack depends on **length of the key**, **time constraint**, and **system security mechanisms**

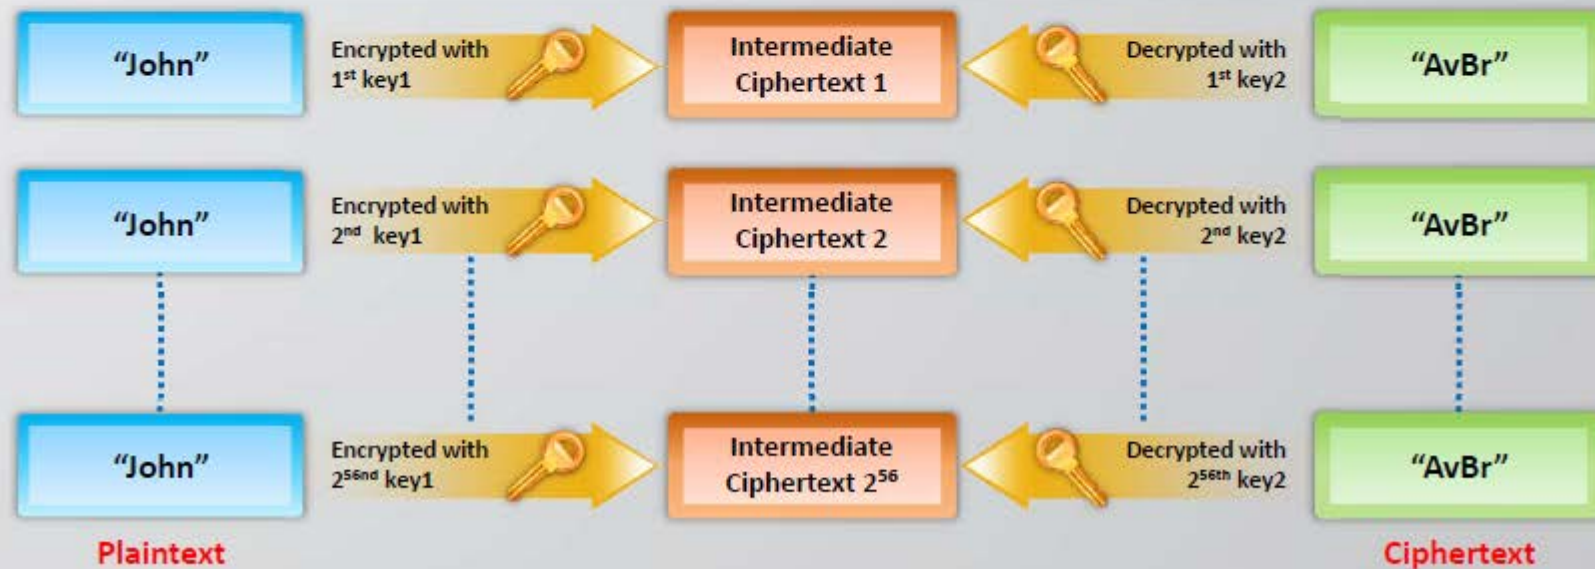

Power/Cost	40 bits (5 char)	56 bit (7 char)	64 bit (8 char)	128 bit (16 char)
\$ 2K (1 PC. Can be achieved by an individual)	1.4 min	73 days	50 years	$10^{20}$ years
\$ 100K (this can be achieved by a company)	2 sec	35 hours	1 year	$10^{19}$ years
\$ 1M (Achieved by a huge organization or a state)	0.2 sec	3.5 hours	37 days	$10^{18}$ years

### Estimate Time for Successful Brute-force Attack

# Meet-in-the-Middle Attack on Digital Signature Schemes

- The attack works by **encrypting from one** end and **decrypting from the other end**, thus meeting in the middle
- It can be used for **forging signatures** even on digital signatures that use multiple-encryption scheme

# Side Channel Attack

**01**

Side channel attack is a **physical attack** performed on a cryptographic device/ cryptosystem to gain sensitive information

**02**

Cryptography is generally **implemented in hardware or software** which runs on physical devices such as semi-conductors

**03**

These semi-conductor devices include **resistor, transistor** and so on

**04**

These physical devices are affected by various **environmental factors** that include: power consumption, electro-magnetic field, light emission, timing and delay, and sound

**05**

In Side Channel attack, an attacker **monitors these channels (environmental factors)** and try to acquire the information useful for cryptanalysis

**06**

The information collected in this process is termed as **side channel information**

**07**

Side Channel Attacks (SCA) are **no way related to traditional/ theoretical form of attacks** like brute force attack

**08**

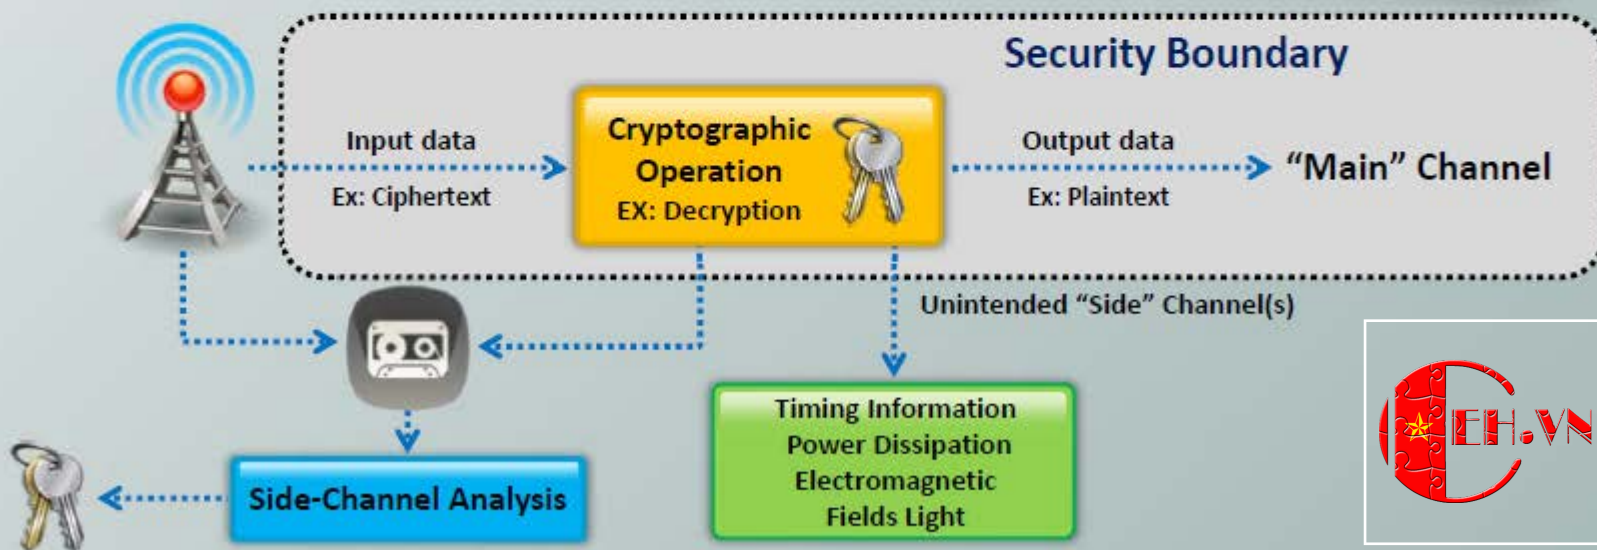

The concept of SCA is **based on the way, the cryptographic algorithms are implemented**, rather than at the algorithm itself

# Side Channel Attack - Scenario

- Assume that an encrypted data is to be decrypted and displayed a plain text, inside a **trusted zone**
- At the time of decryption in a cryptosystem, **physical environmental factors** such as timing, power dissipation etc., acting on the components of a computer are recorded by an attacker
- The attacker analyzes this information in an attempt **to gain useful information** for cryptanalysis

# Module Summary

- ☐ Cryptography is the conversion of data into a scrambled code that is decrypted and sent across a private or public network
- ☐ Symmetric encryption uses the same key for encryption as it does for decryption and asymmetric encryption uses different encryption keys for encryption and decryption
- ☐ Ciphers are algorithms used to encrypt or decrypt the data
- ☐ Hash functions calculate a unique fixed-size bit string representation called a message digest of any arbitrary block of information
- ☐ Public Key Infrastructure (PKI) is a set of hardware, software, people, policies, and procedures required to create, manage, distribute, use, store, and revoke digital certificates
- ☐ Digital signature used asymmetric cryptography to simulate the security properties of a signature in digital, rather than written form
- ☐ Disk encryption protects confidentiality of the data stored on disk by converting it into an unreadable code using disk encryption software or hardware
- ☐ Cryptography attacks are based on the assumption that the cryptanalyst has access to the encrypted information
